Other names for an OPL are solo, sole-charge librarian, or one-man band. The movement, and even the term OPL, can be attributed to Guy St. Clair, the original founder of *The One-Person Library: A Newsletter for Librarians and Management*.

INTRODUCTION

A one-person librarian (OPL) is a person who works in a one-person library. What does that mean? An OPL is the only librarian (or only professional librarian) in a library or information center. The OPL does everything from acquisitions, cataloging, circulation, and reference, even dusting the shelves and vacuuming the carpet, if necessary. It is a situation in which there are no professional peers with whom to share problems and ideas, or to commiserate with when things get tough. The OPL often does not have to go through layers of administration to get approval for purchases or new programs. OPLs know exactly what is going on their libraries: what is being checked out, what questions are being asked, who is using the library, etc. The OPL is often perceived as the “information guru” in the organization—the one to whom everyone comes for answers. Finally, any and all successes (and, of course, failures) of the library are also those of the OPL. They can make of it whatever is in their vision and power.

Other names for an OPL are solo, sole-charge librarian, or one-man band. “Until about twenty-five years ago, one-person librarianship as a recognized branch of specialized librarianship and information services did not exist.”^[1] The movement, and even the term OPL, can be attributed to Guy St. Clair, original publisher of *The One-Person Library: A Newsletter for Librarians and Management*.

Although there are OPLs all over the world, this entry focuses on their history and activities in English-speaking countries, mainly the United States, Canada, the United Kingdom, and Australasia.

BRIEF HISTORY OF THE OPL MOVEMENT

1972: Guy St. Clair was invited to lead a discussion at the 1972 Special Libraries Association (SLA) annual conference in Boston, Massachusetts, on “The One-Man Library.” He said he would do so only if the title was changed to “The One-Person Library.” This is the first instance of the term OPL being used. Hundred of OPLs attended the session, overflowing the room.

1976: St. Clair’s first article on the OPL was published, followed by several workshops and seminars.

1984: St. Clair founded *The One-Person Library* newsletter with Andrew Berner.

Early 1980s: The One-Man Bands group of Association of Special Libraries and Information Bureaux (ASLIB) was formed in the United Kingdom. The group is no longer active.

1986: The first book on OPLs, *Managing the One-Person Library*, was published by St. Clair and Joan Williamson.

1986: The One-Person Library Support Group was established as part of the Toronto, Canada, chapter of the SLA. First chair was Penny Lipman, Rio Algom, Ltd. This is the first OPL group we know of anywhere in the world. It is still very active.

1987: The first 2-day continuing education course on one-person librarianship was taught at the SLA annual conference in Anaheim by Guy St. Clair, who taught similar courses until 1998.

1988: At the SLA annual conference in Denver, Martha Rose (Marty) Rhine led two roundtables on one-person libraries. She circulated a list to obtain participants’ names

and addresses so they could keep in touch. Ninety-nine people signed the list.

1988: Using the list as a base, Marty formed the Solo Librarians Caucus of the SLA, with an initial membership of about 100.

1991: The Solo Librarians Caucus became a full-fledged division of the SLA. Judith Siess was the first chair.

1991: Guy St. Clair was inaugurated as president of the SLA.

1991: *The Best of OPL* was published, consisting of selections from the first 5 years of the newsletter.

1995: One-Person Australian Librarians (OPAL) was formed as a special interest group of the Australian Library and Information Association after the Health, Law and Specials Conference in Sydney. Georgina Dale, Toni Silson (now Kennedy), and Therese Bendeich were its first leaders.

1996: The first German OPL Roundtable was held, organized by Evelin Morgenstern of the Deutsches Bibliotheksinstitut/German Library Institute (DBI), Berlin, Germany.

1997: AspB (the German Special Libraries Working Group), devoted its biennial conference to small special (OPL) libraries.

1997: VdDB (Verein der Diplom-Bibliothekare), an association of professional librarians in Germany, established the OPL Kommission, with Regina Peeters as chair. This special working group offers continuing professional education programs for OPLs at least twice per year.

1997: *Das Robinson-Crusoe Syndrom und was man dagegen tun kann* (The Robinson Crusoe Syndrome and What You Can Do About It) was published, with reports from 24 German OPLs describing their work.

1997: The Solo Librarian's Sourcebook by Judith Siess was published.

1997: The first meeting of Special Librarians (many of them OPLs) in the Midlands (SLIM) was held in Birmingham, England. Chris Crabtree and Margaret Brittin were the founders.

1998: A Most Delicate Monster: The One-Professional Special Library by Jean Dartnall was published in Australia.

1998: Information Bridges International purchased *The One-Person Library* newsletter. Judith Siess was the new editor/publisher.

1999: Special Librarians in London (SLIL) was founded by Bert Washington of Sports Marketing Surveys. This function is now fulfilled by the Industrial and Commercial Libraries Group of CILIP.

1999: The Workplace Libraries discussion list was launched April 1999, by the Library Association (now CILIP, Chartered Institute of Library and Information Professionals; United Kingdom). (Now discontinued.)

1999: An electronic discussion list just for OPLs was established by the Library Association. (Also discontinued.)

1999: The Workplace '99 Initiative was started by the LA to increase awareness of commerce, industry, government, and voluntary institution libraries. Lyndsay Rees-Jones and Mark Field are the LA Professional Advisors for Special Libraries. (Discontinued, but Rees-Jones is still actively assisting solos.)

1999: A Solo Professional network was set up by Steve Witowski of the East Midlands Branch of the LA. (No longer active.)

2000: The first meeting of Special Librarians in Cambridge (SLIC) was held in England. Lis Riley was the founder. (Still active.)

2000: OPAL published its first book, *Evaluating Websites*.

2000: Initiative Fortbildung für wissenschaftliche Spezialbibliotheken und verwandte Einrichtungen (Initiative for Special Libraries and Similar Institutions) was formed in German as DBI was being dissolved.

2004: The OPL Archives were established by Judith Siess at the University of Illinois at Urbana-Champaign (where both she and Guy St. Clair received their library degrees). Material in the archives includes copies of all issues of *The One-Person Library* newsletter; books on OPLs from the United States, the United Kingdom, and Australia; copies of many articles by and about solos and OPLs.

2005. *The Essential OPL, 1998–2004: The Best of Seven Years of The One-Person Library: A Newsletter for Librarians and Management*, was published by Judith Siess, with Jonathan Lori.

2006. *The New OPL Sourcebook* was published by Judith Siess.

How many OPLs are there? Because of their size, there is no accurate count of OPLs, but the following figures are available. The SLA estimates that close to 60% of their more than 11,000 members are OPLs. That is nearly 7000 OPLs in special libraries alone! (The Solo Librarians Division of SLA grew to nearly 1000 members before a decline that paralleled that of SLA as a whole. In 2007 there were nearly 700 members, the fifth largest division in the organization.) A large percentage of U.S. public libraries have no more than one professional librarian. Most school libraries have only one professional (if that many), as do most hospital libraries. Small law firms are unlikely to have more than one professional, and prison and church or synagogue libraries are lucky if they have any degreed staff. There seems to be a consensus that about one-third of the world's libraries are one-person or one-professional operations.

WHERE DO OPLs WORK?

Most OPLs work in special libraries. A special library is one serving a specialized or limited clientele, with specialized or limited materials and services. The emphasis is

often on providing information, rather than on books. The collection is usually small. The OPL nearly always reports to a nonlibrarian, and the library is part of, but not considered critical to, the parent organization's main mission. Most OPLs (about 80%) are solo by chance, with only 20% by choice. However, a lot of OPLs that started by chance now like it so much that they would not go back to a large library.

According to St. Clair and Williamson,^[2] a library with an OPL may be the organization's first library, newly established and unsure of how many staff it needs, destined to grow to include a larger staff. It can also be a downsized library, formerly having several librarians, but due to less demand, less money, or less awareness of need, now be reduced to one professional. Or, it can also be a right-size library, one that needs only one well-trained and efficient professional to serve the organization's information needs. This is probably the most common situation.

Although many OPLs work for corporations, there are other opportunities. Following are just a few of them.

Law Libraries

Librarians serving private practice or small law or bar associations are often OPLs, as are law librarians in government institutions such as courts or agencies, and some public law libraries, but these make up only about 15% of law librarians. Most law librarians in academia and law schools, where a library is required for accreditation, are not OPLs. Only 29% of law librarians have law degrees, but nearly all (80%) have library degrees. Most employers look to their law librarians to save billable hours of the lawyers, to save attorneys' time and billable hours looking for information, and to add to revenues by having the librarian perform billable information searches for clients. Sometimes they are also looking for other capabilities, such as archives, records management, managing dockets, conflicts checking, and supervising paralegals. The future will probably see an expansion of the law librarian into other areas, including skill-based resource management, client current awareness services, research for client and practice development, supporting speaking opportunities (speeches and seminars), research or reference and/or technology training for clients, internal and client newsletters, web page design, content, management, coordinating continuing legal education programs, managing paralegals, and formal legal research training for new staff. (Note: If librarians are asked to perform research for clients, they should be sure it is included in the firm's profitability analysis.) The issues facing legal OPLs are the need for rapid delivery of information, often with price insensitivity; the currency and accuracy of the information; the high degree of confidentiality expected; deciding the fine line between legal research and interpretation; and dealing with summer interns or law clerks. Also, academic

law librarians are becoming increasingly responsible for teaching legal research techniques to students. Other issues not unique to law librarianship are timeliness, currency, accuracy, thoroughness, detail, rising costs, and burnout, and an emphasis on the practical uses of information. Academic law librarians get more involved in research, history, and comparative law. In a summary of several studies of how lawyers find information, researchers found that 50–60% of them do not go to librarians for help, even if they have trouble finding the information themselves. They do not use the librarian to learn how to search, only to provide the documents they identify from their own search.

Prison or Jail Libraries

Most states require the provision of access to legal materials to inmates (although some have decided to close all their prison libraries). Most prison libraries remain one-person positions, despite staffing-level recommendations. Most prison librarians are professionals. Prison librarians have problems motivating their inmate assistants due to turnover and lack of a strong work ethic. They are also concerned with confidentiality, and the dividing line between legal reference and legal advice. Another hot current issue is the computerization of prison libraries. Prisons are reluctant to replace books with computers because of the potential for online crime. Jail libraries are usually smaller and less likely to hire a professional. The emphasis is on access to legal materials and recreational reading as a form of behavior control or self-improvement. Lack of funds, censorship, and low status are major issues. Personality traits needed by prison or jail librarians include an understanding of the political climate of the institution, survival skills, patience, a sense of humor, ability to follow the rules, and a professional demeanor.

Hospital Libraries

Hospitals used to be required to employ professional librarians for accreditation; however, they are now only required to provide access to appropriate materials. However, most hospitals still have libraries and librarians. Except in the large medical schools and hospitals, the librarian is often an OPL. The needs of physicians are similar to those of lawyers—rapid delivery of current and accurate information, price irrelevant, and with a practical application. Many hospital librarians are also involved in patient service, archives, consumer health information, and administration of physician continuing education. Some librarians are even part of the treatment team—this practice is increasing with the advent of higher training levels for librarians and the computerization of medical information. Hospital libraries frequently have a staff of volunteers of varying degrees of training and commitment with which to work. This may or may not help the OPL's

workload. The Medical Libraries Association offers a certification program in medical librarianship. Although certification is not required for all medical librarian positions, it is strongly encouraged.

Museum or Zoo Libraries

Museums, zoos, and libraries acquire, describe, and make accessible to us the records of human experience, covering life sciences, education, business, philosophy, and art. Not all museums or zoos have libraries. The American Zoo Association/Librarian Special Interest Group (AZA/LSIG) consists of zoo and aquarium librarians, as well as individuals in zoos and aquariums that are responsible for their institution's library and operations. Formed in 1978, AZA/LSIG now has more than 90 members from zoos and aquariums spread across three continents. Some zoos use volunteers to staff their libraries, whereas many others combine the job of librarian with another position. These libraries have historically been underfunded, understaffed, and underused. Facilities range from just a collection of books and magazines for staff use to a fully organized and professional-directed information collection. The library is likely to have a relatively large number of volunteers. Nearly all the libraries provide reference service to staff, members, and the general public. Few circulate items beyond the staff, provide online searching, perform document delivery, or have access to the Internet.

Church or Synagogue Libraries

Many churches and synagogues have libraries. Some are staffed by volunteers (often a retired librarian or schoolteacher), but some of the larger ones hire professional librarians. Nearly all these are one-person positions. The church library functions as a centralized place for materials for church programs (a sort of learning and resource center), with the specific aim of promoting the spiritual development of its users. There are no specific educational requirements for the church librarian, but dedication, friendliness, ability to work with details, neatness, patience, and a sense of humor are suggested—the same criteria as for an OPL. Funding is usually minimal, as is pay, but it is a rewarding field for the dedicated.

Public Libraries

Surprisingly, a large number of OPLs work in public libraries. Nearly 80% of public libraries serve populations of fewer than 25,000 and are staffed by no more than one professional.^[3] The library director is the heart of the library, representing the library to the community, the board, and the staff. Public librarians face similar issues as corporate or other types of librarians: a sense of intimacy with their patrons, overwork, doing it all, dealing with nonlibrarians as supervisors (the library board). The

librarian and the board are often at odds about the role each should play. OPLs in public libraries also face some unique issues: building maintenance, bond issue, etc. Another issue unique to public libraries is the relationship to the school system. Some communities may not understand the necessity to support two separate library systems. Pay for directors of small public libraries is often abysmal; there are personnel issues and long hours, but, as with all OPLs, you run the show.

Public or Private School Libraries

School librarians and media specialists are often OPLs. Many of them serve two or more school libraries, with volunteers (often students) staffing the library when the librarian is not there. All professional school librarians must also have a teaching certification. They are seen as an extension of the classroom and often assist teachers with special projects, as well as running the library and teaching library skills to the students. Some even have such varied duties as story hours, teaching reading or English, computer instruction, advisor to student groups, running the bookstore, and lunchroom supervision.

Information Brokers

The work of information brokers falls into two main categories: information retrieval and delivery, and information organization. The latter is often called information consulting. He or she may design and produce databases, perform primary and secondary research, obtain documents, perform abstracting and indexing, evaluate libraries, manage libraries, perform outreach and public relations, perform translations, act as a records manager, train librarians, write or edit books, articles, or newsletters—or almost anything else you can imagine. What does it take to be a successful information broker? Patience, speaking and writing and telephone skills, organizational skills, a sense of humor, ability to integrate disparate concepts, problem-solving ability, perseverance, broad base of knowledge, dedication and hard work, enjoying working alone, ability making decisions, ability to prioritize, energy, intelligence, creativity, computer skills, confidence, optimism, and the ability to sell yourself and your services—in other words, the same skills as a good OPL.

Market Researchers

An increasing number of librarians work in the competitive intelligence (CI) field, usually as OPLs. CI is the gathering of information that will assist a company in maintaining its competitive edge. (It is not, as some think, only gathering information about one's competitors. It also includes information about a company's customers, keeping up with technology and anything else that makes

the company better able to compete.) Librarians are exceptionally well qualified to do CI, being trained to search for, analyze, organize, and disseminate information. They are experienced in working in an interdisciplinary environment. They already have their own networks. Other traditional library competencies that transfer well to CI include online searching, the reference interview, current awareness, knowledge of bibliographic tools, computer skills, written presentation skills, and time management.

Other Opportunities

The nontraditional sector is probably the fastest-growing area of librarianship. A librarian's skills can be applied in many fields. One can be a representative for a library supplier, a writer or publisher, a consultant, work for a market research firm, a not-for-profit organization, a government agency, a document delivery service, an association library, in website development, or for a library consortium or network. Job opportunities are limited only by your imagination, creativity, interest, and persistence.

WHAT DOES AN OPL DO?

The tasks of an OPL fall into the following categories:

Managerial

- Manage any clerical employees or volunteers available, including hiring, discipline, and firing.
- Manage one's own time, including learning to deal with interruptions.
- Create and distribute publicity for the library. This may include a weekly newsletter, articles in the organization's publications, and open houses.
- Organize library files and, because there is no one else to do it, file.
- Write monthly and annual reports to management.
- Prepare, distribute, and evaluate user surveys to determine user desires, attitudes, and satisfaction.
- Keep and analyze a wide variety of statistics.

Technical

- Locate, evaluate, and order books and magazines, often for the entire organization, not just the library.
- Follow up on orders.
- Check books and magazines in and out, and keep statistics on what is and is not being used.
- Answer questions from people within the organization, whether they come in by telephone, mail, e-mail, fax, or in person. These requests for information may use resources in the library or involve ordering articles from another library. Often these are "rush" requests

with a deadline that can be as short as within the hour. Other questions involve extensive research and a written summary.

- Teach users how to find information, in the library and on the Internet.
- OPLs are often in charge of the organization's audio-visual equipment (slide projectors, etc.).
- Evaluate new electronic services and sources; arrange a demonstration or trial period, if possible; and recommend or make the final purchase decision. This may include computer, systems, and software, too.
- Troubleshoot or repair equipment such as computers, photocopiers, printers, and even entire networks.
- OPLs are often asked to create web pages for an organization's Intranet or Extranet, and sometimes serve as the organization's webmaster.
- In addition to the above, OPLs are often in charge of an organization's archives or records. OPLs in hospitals are often given responsibility for tracking physician continuing medical education and/or patient or consumer education materials.

Professional

- Participate in local, regional, national, or even international library organizations and networks. OPLs often serve in leadership positions.
- Keep up with the library and information worlds by reading professional literature and following electronic discussions.
- Arrange for one's own continuing education—attending seminars, professional conferences, and courses.

Financial

- Pay bills.
- Purchase office supplies, catalog cards, copy paper, computer media, etc.
- Prepare the library budget.
- Track library expenses.

Why would anyone want to be an OPL? The three most common reasons are independence, variety, and an enhanced feeling of self-worth. OPLs enjoy the ability to run their show, plan their own schedule, and set their own priorities, with a minimum of supervision (and interference). The life of an OPL also has its drawbacks. The most commonly mentioned problems are professional isolation, lack of clerical support, the need for reporting to a nonlibrarian, and low pay.

Because many OPLs are OPLs by choice, obviously the pros must outweigh (or at least equal) the cons. Perhaps the key is in fitting the right person to the job. Most people agree that an OPL should be flexible and creative, biased toward service, able to share and build coalitions,

idealistic, resourceful, curious, self-confident, and patient. In addition, the OPL should be able to work alone; manage time, think analytically, and see the big picture; have a sense of humor, good organizational skills, good recall, excellent oral and writing skills, and a high tolerance for frustration. Can these skills be taught? They probably cannot, but the specific tools and techniques to make the most of them can be learned, either in library school, on the job, or through continuing education. An OPL must also have confidence in making good decisions, an entrepreneurial attitude, comfort with networking, proficiency in gathering supporters, a lot of flexibility, good time management and balancing of priorities, a love for the profession, ability to cope with lots of bosses and patrons who think they are the only client, a readiness to take risks and learn something new every day, a passion and enthusiasm, and a willingness to dive in to do anything.

HOW DOES AN OPL HELP THEIR ORGANIZATION ACHIEVE ITS GOALS?

All employees must be involved in their organization's goals, but this is especially important for OPLs. They must ensure that the library is seen as a critical part of the organization and that it is involved in mission-critical issues. The library's mission statement must closely mirror the mission of the organization. The library must also be relevant to the lives of its users. The OPL knows more about the organization and its business, the users and their needs, and how to collect, organize, and disseminate information than anyone else in the organization because of its strategic position as the information hub.

Power makes organizations run. An OPL must know the organization's corporate culture—its shared beliefs, values, and assumptions. The OPL also learns how the organization is formally structured and how it actually works, who is in power and who is not; what information the organization needs, who needs it, how it flows within the organization, team dynamics, and communication.

The OPL's customers are management, other professionals, secretaries and other clerical staff, manufacturing workers, the mailroom, and perhaps even the cleaning staff. All these are potential customers of the library. Ideally, all should be treated equally, but it would be foolish not to recognize that one will be much faster to respond to an inquiry from the president or managing director of the organization than from a worker on the assembly line. However, it is the importance of the answer to the continued existence of the organization, not the position of the customer on the organizational chart that matters. Users do not want information, they want answers. They want their problems solved. This answer could be an article, a book, a list of references or websites, or even a summary report with the answer to the question. This is how the library can best add value. Clients also expect the library to help lower

their cost of doing business—by saving them time and, therefore, money. Another way the OPL helps the organization is by making information convenient for them. This can mean anything from taking requests over the Internet to putting databases and research services on their desktops.

OPLs must be proactive and anticipate what customers will need and be sure they can meet the demand. This involves planning, thinking, anticipating, and taking the initiative. The keys are communication with and to customers, and taking responsibility for information (evaluating it for content and quality). OPLs find out what customers need by observing, listening, and reading both the library and industry literature.

The OPL should also be involved in "knowledge management." Knowledge management is the art of making creative, effective and efficient use of all the knowledge and information available to an organization all for the benefit of clients. Its implementation requires a review of the organization's values, culture, infrastructure, and management of intellectual assets. Knowledge management is a new focus on information and knowledge, creating a knowledge-valuing environment, where information is shared, managed, and used. Librarians in general, and OPLs in particular, are perfectly situated to be the knowledge management leaders in an organization. They already understand the organization and its information flows. Their people skills and customer service orientation allow them to work well with all levels of the organization, from the factory floor to the highest levels of management. They can find information, evaluate it, and produce analytical reports of its significance.

THE FUTURE OF ONE-PERSON LIBRARIANSHIP

Librarianship will increasingly depend on technology. However, the computer or the Internet will not be able to answer every question, will not replace the human touch, and cannot greet the user with a smile. Technology must be seen and designed as just another tool to solve problems, not an end in itself, leading us only to find new ways to use new technology. The costs, benefits, and impact on users of any proposed innovation must be weighed before its adoption.

Many people expect that the information user of the future will not have to come to the library at all, relying on Internet, phone, or e-mail access. Libraries may indeed go virtual, but there will always be a need for a physical repository somewhere and someone to decide what to put in it, devise an order for it, and arrange access to it.

More and more librarians, especially OPLs, will be working outside libraries in an organization or on their own. The location of a librarian in a physical library may be unnecessary and, in some cases, undesirable. In the corporate sector, librarians are moving out of the library into the business units, working alongside other professionals to provide the information needed for informed decisions right

at the point of the decision. Partnering or team-building skills will become even more vital in the future in the corporate world. This is also important outside the for-profit arena, as librarians are increasingly required to work as part of research or project teams in organizations, participate in clinical rounds in hospital rounds, and support teams of attorneys working on large, involved cases. In the electronic future, the librarian's world will become wider.

Medical librarians are already moving out of the library and into the future. One example is clinical librarianship, where the medical librarian receives special, accelerated medical training and then becomes a part of the patient team. The librarian accompanies the physicians on rounds. Equipped with a laptop computer, a wireless modem, an Internet connection, and access to medical databases, the librarian can often provide instant answers to clinical questions. When the answer cannot be found immediately, the librarian returns to the library (or their desk or cubicle) and engages in a lengthier search, delivering the answer (not raw data or articles) to the physician within hours.

Instead of OPLs being downsized out of existence as many fear, it is likely more will be created. Some of these will be, unfortunately, from the downsizing of larger libraries, but many more will come from the realization that information is absolutely necessary for an organization's success and that a trained information professional, that is to say a librarian and not a computer person, is the best one to handle this responsibility. To quote St. Clair:

[managers] will find that they get more value for their money by employing one highly skilled and effective librarian/information specialist instead of a team - however small - of generalists who are not as skilled. There is also recognition in the profession that one-person librarianship just might become a standard for library staffing in the future. [Often] one excellent, efficient, and enthusiastic librarian or information specialist is preferable to two or more who do not provide the same level of service for users.^[4]

Although there have been drastic changes in the information climate since he wrote these words, the desire for good library service or good information delivery has not changed. Because of the following, the OPL more than ever is able to serve an organization's information needs with little or no assistance:

- Advances in technology, including networking, electronic information available online or on the Web at little or no cost (in money or time)
- Concentration of librarian resources on mission-critical functions and outsourcing or elimination of nonessential services
- Increasing capability of users to find answers to noncomplex questions, or for law librarians or attorneys using electronic resources to perform their own

legal research, thus allowing librarians to focus on business, medical, or international issues

- Better training and education for librarians in general and OPLs in particular; a heightened sense of professionalism by OPLs, accompanied by more attendance at continuing education events; and increased interpersonal networking and establishing of professional cooperative relationships

There will, of course, continue to be challenges. The idea that "everything is on the Internet and is free" is a serious problem. OPLs must show their clientele that they have only found the tip of the information iceberg and the rest can best be found with the assistance of a librarian. A second major challenge is downsizing. All librarians, but OPLs in particular, need to demonstrate their value to management on a daily basis. They have a responsibility not only to keep the information professional in the organization, but also to demonstrate to future generations of librarians how great it is to be an OPL.

Fundamentally, OPLs around the world are the same; yet, there are some critical differences. The concept of one-person librarianship has not been well known outside the United States, Canada, the United Kingdom, Australasia, and Germany. Although there undoubtedly are many OPLs around the world—in fact, they may predominate—there is no good way of reaching them. They are most likely working in "less-developed" nations in small libraries in small communities or charitable institutions, and are unlikely to be degreed librarians (or to have even had any library training at all). Managers and even library directors are not library professionals. Library work is not valued. Job responsibilities for trained librarians may be limited to technical processing (choosing books, cataloging them, checking them in and out), with no time for helping people with their information needs.

The full potential of technology is unrealized in much of the world. Even e-mail and electronic lists cannot be used because some of the smaller libraries do not have access to a network, but need to dial up to use their e-mail and they only get the chance to do this once or twice per day. Some libraries do not even have a computer. In many countries, library resources and organizations are less plentiful. Problems with currency fluctuations and the resultant high cost of online services and journals can cause major problems for many OPLs. Educational systems outside the United States are structured quite differently. There is not always an emphasis on customer service.

It is almost certain that there will be more OPLs in corporate and other institutional settings, and probably even in public and academic settings. Although some may see this as a bad thing, it can be an opportunity for those who enjoy working alone. Networking is now and will continue to be imperative for survival. Fortunately, this is getting easier every day. There are multitudes of electronic discussion lists. Organizations serving OPLs are

growing and beginning to cooperate. For those in developing countries, networking is even more important. Therefore, it is incumbent on experienced OPLs to establish and maintain mentoring relationships with OPLs elsewhere so that they will no longer feel alone.

Online Catalog Subject Searching

Danny C.C. Poo

School of Communication and Information, Nanyang Technological University, Singapore

Abstract

The Online Public Access Catalog (OPAC) is an information retrieval system characterized by short bibliographic records, mainly of books, journals, and audiovisual materials available in a particular library. This, coupled with a Boolean search interface and a heterogeneous user population with diverse needs, presents special problems for subject searching by end users. To perform effective subject searching in the OPAC system requires a wide range of knowledge and skills. Various approaches to improving the OPAC design for subject searching have been proposed and are reviewed in this entry. The trend toward Web-based OPAC interfaces and the developments in Internet and digital library technologies present fresh opportunities for enhancing the effectiveness of the OPAC system for subject searching.

OVERVIEW

An OPAC database records are usually derived from the MARC (MACHine Readable Cataloging) format. The records are brief bibliographic descriptions enriched with a small number of controlled subject descriptors (often taken from the Library of Congress Subject Headings) and a classification number (usually a Library of Congress or a Dewey decimal class number). The database records, thus, contain minimal information for searching—little more than the author, title, publication year, subject description, and a class number.

The subject descriptors are selected to reflect the subject content of the item as a whole rather than to provide in-depth indexing of the information contained in the item.^[1] For example, if a book contains many articles, subject descriptors are not assigned for each article but only to the overall topic of the book.

For periodical publications, only the periodical as a whole is described. Individual journal articles are usually not recorded in the database. This is in contrast to indexing and abstracting databases that provide keyword searching in the abstract and even the full text of articles, and provide exhaustive indexing of the content of journal articles. However, the distinction between OPACs and other kinds of information retrieval systems is blurring. Increasingly, OPACs are also providing links to full-text document, electronic books, and Internet resources.

Most of the online catalogs in use today are what Hildreth^[2] termed second-generation OPACs. Most

OPACs are Boolean retrieval systems that perform exact matching and require the search query to be specified as a Boolean expression. Typical search features include the choice of keyword searching (i.e., searching for individual words in the title and subject fields) or field searching with automatic truncation (e.g., searching for a whole title or author name), the use of Boolean operators to combine two or more terms, the use of a truncation symbol, and limiting a search to specific fields. *The onus is on the user to translate the user's information need into the subject headings and indexing terms used in the OPAC database and to refine the search based on the initial search result.*

Because most OPAC systems now offer Web access, OPAC interfaces are increasingly Web interfaces in the form of web pages containing HTML forms. Such interfaces are mainly form-filling interfaces. The user selects the type of search and the fields for searching either by entering the query in the appropriate input box or by toggling the appropriate checkbox or radio button. For keyword searching, the search expression can include Boolean operators as well as indications of which field(s) to search.

OPAC users are heterogeneous, varying widely in background, age, subject interests, and computer and information literacy. So the OPAC has to be designed to cater to a wide range of users, ranging from users who have little knowledge of what a catalog contains and have little experience with computer terminals to librarians who are experienced in online database searching and who require the system to have powerful search capabilities.

SUBJECT SEARCHING

OPAC searching is of two types:

- Specific-item searching (or known-item searching), where the user is trying to locate a particular item that the user knows of and has some information about (e.g., the author or fragments of the title)
- Subject searching, where the user wants to retrieve any item(s) on a particular topic.

The distinction between these two types of searching is fuzzy. A search often involves both types of searching. What begins as a specific item search often ends up as a subject search, especially if the specific item search fails to locate the desired item. Both types of searching have their particular problems. This entry focuses on the problems with subject searching.

Slone^[3] distinguished between two types of subject searching: unknown item searching and area searching. In an area search, the OPAC is used to identify the area in the library where materials on a particular topic are located. Online searching is kept to a minimum, and the user relies on shelf browsing to identify specific relevant items. In contrast, unknown item searchers rely on the OPAC to identify the specific relevant items.

Subject searching is an important activity that constitutes a major proportion of OPAC searches. However, estimates of the proportion of subject searches vary, partly because the proportion varies with the type of library and user group, and partly because of the practical difficulty of distinguishing subject searches from other kinds of searches.

In a nationwide survey of U.S. libraries in the early 1980s, Matthews et al.^[4] found that about 59% of online catalog use involved subject searches. Recent studies of OPAC transaction logs obtained percentages of subject searching ranging from 35 to 60%.^[5–10] It is possible that the actual proportion of subject searching is even greater than reported because some of the keyword title searches actually represent subject searching.

A number of studies found subject searching to be the most common type of OPAC searching,^[6,9,11] although other studies found a decline in subject searches and an increase in title searches.^[10,12,13] Two studies of university OPAC use found that undergraduate students tend to do subject searching, whereas graduate students and faculty tend to search by author or title and do subject searching only when working outside their own fields.^[13,14]

KNOWLEDGE NEEDED FOR SUBJECT SEARCHING

To perform effective subject searches requires the following kinds of knowledge:

1. Knowledge of the fields in the bibliographic records that can be used for subject searching and their characteristics.
2. Knowledge of the thesaurus system or subject headings list from which subject descriptors are selected and assigned to each bibliographic record.
3. Knowledge of search strategies and when and how to apply them.
4. Knowledge of the search capabilities provided by the OPAC system and how to use them.
5. Knowledge of the subject area.
6. Knowledge of how to translate an information need into a searchable query.

Borgman^[15] divided the knowledge needed into three types:

1. Conceptual knowledge of the information retrieval process—how to translate an information need into a searchable query.
2. Semantic knowledge of how to implement a query in a given system—how and when to use system features.
3. Technical skills in executing the query—basic computing skills and the skill of formulating search statements in the syntax required.

The main fields in the bibliographic record that contain subject information are the title fields, subject fields, and class number fields. Each subject field contains a subject descriptor or subject heading selected from the Library of Congress Subject Headings (LCSH) or from some thesaurus [e.g., the U.S. National Library of Medicine's MEDical Subject Headings (MESH)]. A subject descriptor comprises a main descriptor and optionally a number of modifiers called subheadings or subdivisions. To know what descriptor and modifiers to use when searching the subject field, the user has to consult the Library of Congress Subject Headings or thesaurus, which may be searchable online or available only in printed form.

Knowledge of the thesaurus structure, how the descriptors are selected to represent the subject content of a work, and how the descriptor–modifier combinations are constructed is important for searching the subject field effectively. Knowledge of the thesaurus structure includes knowing the kinds of relations (broader term, narrower term, related term, etc.) used in the thesaurus and how to make use of these relations.

In selecting terms to search in the subject field, users should be aware of the following two principles used by indexers when selecting descriptors from the thesaurus:

1. Descriptors are selected that summarize the content of the whole item rather than index all the concepts contained in the work. This suggests that when searching the subject field, the user should use a term

or descriptor that is broader than the concept of interest.

2. When selecting a descriptor to represent a concept in a work, the most specific descriptor that matches the concept is used (the rule of specific entry), and usually only one descriptor is used to represent a concept. An item that is assigned the descriptor "Fishes" will usually not be assigned descriptors for specific types of fish (e.g., "Sharks" or "Goldfish"). So, to locate books on all kinds of fishes, the descriptor Fishes and all narrower terms should be used for searching.

An alternative way of doing subject searching is to search for keywords in the title and subject fields. Keyword searching in the title field is particularly appropriate when there is no descriptor that matches exactly the concept that the user is interested in. The disadvantage is that a concept may be expressed by several synonymous words, each having several variant forms, and that all the synonyms and variant forms have to be used in the search to retrieve all the relevant records. In addition, keyword searches may retrieve many nonrelevant records if the keyword has more than one possible meaning.

One field that is often overlooked in subject searching is the class number field. To search this field effectively requires knowledge of the classification system and notation used. The user also needs to consult the appropriate classification schedule to identify the correct class numbers to use. The major advantage of class number searching is that it allows the user to browse neighboring numbers and find related works. This is similar to browsing at the shelves. One problem with the class number search is that only one class number is assigned to an item, even if the item covers more than one topic.

Author fields can also be used for subject searching, inasmuch as publications by the same author tend to be on the same or related topics.

Although most online catalogs have subject, title, class number, and author fields, the catalogs vary in the search capabilities provided, in the search language used for searching these fields, and in the design of the search interfaces. To perform effective subject searches, the user needs to know the search features available and how to use them.

Also needed is the more general skill of translating an information need into a searchable query. This may involve visualizing what information is needed to satisfy the need, the kind of book that is likely to contain the desired information, the content or topic of the book, and the terms that can be used to represent the topic. Some knowledge of the subject area is needed to think up broader terms, narrower terms, and related terms for searching and for looking up appropriate descriptors in the thesaurus.

Slone,^[3] in a study of OPAC use in a public library, found generating search terms was crucial to a successful unknown item search. When term generation was difficult,

unknown item searches failed. She found that users who performed very narrow searches tended not to find what they needed. Users who performed broad searches and then narrowed the search, by selecting terms from the search results to use in a new search, were more successful. However, many users had so little knowledge of what they sought that they were not able to generate related terms to initiate a search.

An appropriate search strategy is thus needed to apply all the above knowledge creatively to perform an effective subject search. Search strategies can be divided into initial strategies and reformulation strategies. Initial search strategies are used in formulating the initial search request. Reformulation strategies are used for formulating subsequent search requests to improve the search result after reviewing the initial search result. Reformulation strategies include broadening strategies for increasing the number of relevant records retrieved and narrowing strategies for decreasing the number of unwanted records retrieved.

PROBLEMS USERS HAVE WITH SUBJECT SEARCHING

Numerous studies using a variety of research methods have found that users have difficulty performing subject searches in online catalogs. Problems experienced by users include the following:^[8,16-18]

- Users have difficulty matching their search terms with those used in the online catalog.
- They have difficulty identifying terms that are broader or narrower than their topic of interest.
- They lack understanding of the thesaurus structure and the Library of Congress Subject Headings.
- They don't know how to broaden the search and increase the search result when too little or nothing is retrieved.
- They don't know how to narrow the search and reduce the search result when too much is retrieved.
- They don't know how to use Boolean operators and truncation and how to limit keyword searches to specific fields. They are generally not aware of the more sophisticated capabilities of the OPAC system.
- They don't know how to translate their information need into a Boolean search statement.
- They have difficulties with spelling.
- They have difficulty formulating a search command using the search language of the system.

Slone^[3] found that 60% of unknown item searchers in a public library OPAC were frustrated and 40% were disappointed. Only 20% were relaxed or content.

To obtain optimal results in subject searches often requires using more than one search strategy. The typical online catalog user does not know the range of strategies

that can be used or the limitations of each strategy. Users lack much of the knowledge described in the section “Knowledge Needed for Subject Searching” above.

A high proportion of OPAC subject searches result in null sets or zero postings.^[6–8,19] Spelling and typographical errors are among the most common errors.^[7,8,10,19] More help is clearly needed to help users recover from spelling and typographical errors and guide them to related terms that may retrieve items with useful information.

Studies of OPAC transaction logs have found that few users make use of Boolean operators in their searches (e.g., Connaway).^[10] Users are also confused about the difference between keyword searching and searching by subject headings. Connaway et al.^[14] found that many users searched the subject field when a keyword search might have been more appropriate. Hildreth^[20] found that most users do not understand how the OPAC system processes their keyword searches.

IMPROVING THE DESIGN OF OPAC SYSTEMS

Numerous writers have suggested how the on-line catalog can be designed to help users perform more effective subject searches. The suggested improvements can be divided into the following categories:

1. Develop more helpful and user-oriented interfaces.
2. Develop graphical and direct manipulation interfaces.
3. Develop interfaces for browsing.
4. Enhance catalog records with more subject and table of contents information.
5. Provide query expansion and query formulation support.
6. Provide non-Boolean best-match search capability.
7. Provide relevance feedback and query refinement capability.
8. Incorporate search heuristics.
9. Incorporate search trees and knowledge-based techniques.

These solutions are briefly reviewed below.

Design More Helpful and User-Oriented Interfaces

Simple changes to the OPAC screen design can help users improve their searching significantly. Such improvements to the OPAC screen can be identified by analyzing the OPAC transaction log. Bleic et al.^[21] analyzed the transaction log of a university OPAC system, identified the main errors made by users, and then made simple changes to the OPAC screen, such as simplifying and clarifying the wording in the introductory screens, using the same book for all search examples, placing the keyword search option as the first option, and making certain help messages more

prominent. An analysis of the transaction log 6 months later found a statistically significant reduction in errors and more effective searches. Ballard^[22] had also found that the amount of keyword searching increased when keyword search was listed as the first option on the OPAC screen. In a follow-up study, Bleic et al.^[23] found that some of the initial improvements did not hold over time, indicating that the same OPAC screen design can affect different user groups differently, especially in a changing computing environment.

Hildreth^[20] found that users seldom read help screens. Nevertheless, they expressed a strong interest in context-sensitive search assistance from the system while conducting their searches. Context-sensitive help messages displayed on the same screen as the search result can guide the user on how to improve the search. When no record or few records are retrieved, the system can suggest shortening the search phrase, substituting synonyms or more general terms, or retrying the search using a different search method. When too many records are retrieved, the system can ask the user to enter additional search words or enter limiting criteria to narrow the search. The messages could tell the user what to do, how to do it, and why it may improve the result.^[24] However, online prompts can provide only a limited amount of help. Some search strategies require an understanding of the bibliographic record, controlled vocabulary, cataloging rules and online searching, and too much information about “what to do, how to do it, and why” will overwhelm the user.

Some researchers have called for OPAC systems to incorporate models of the user and the user’s task and situation. Such an OPAC can provide different search screens, use different search strategies, and guide the user in different ways according to:

- Whether the user is a new OPAC user or an experienced user.
- Whether the user is knowledgeable about the subject area.
- Which stage of a project the user is at.^[25–27]
- Whether the search is a continuation of an earlier search.^[28]
- What the goal of the user is in performing the search.^[27,29,30]

While clearly desirable, it is not yet known how user models can be incorporated into OPAC systems effectively.

Graphical and Direct Manipulation Interfaces

With new developments in interface technology as well as advancements in Internet and Web-related technologies, such as Dynamic HTML, new types of graphical OPAC interfaces are likely to be developed, which incorporate 2-D and 3-D images, animation, virtual reality, and direct

manipulation capabilities that allow users to manipulate objects on the screen. Such techniques can be used to help users visualize relationships between search terms as well as documents and help users to browse the OPAC database. They can also be used to help users understand search strategies and make the manipulation of search results and OPAC records more intuitive. Some ideas for the use of icons, animation, manipulation, and metaphor have been explored in prototype OPACs.

Lee^[31] described an animated, object-based OPAC interface that featured 2-D and 3-D interactive objects such as card catalog drawers, bookshelves, and cassette tapes that could be manipulated. Bovey^[32] described an online catalog for a collection of cartoons. The set of cartoons retrieved in a search was displayed on a time line showing the number of cartoons published on each month and year. The user could use the mouse to point to a place on the time line to select a cartoon published at a certain time. Chung^[33] explored how virtual reality can be incorporated in an OPAC interface.

Pejtersen^[34] described a prototype online catalog of fiction materials called the Book House, which used the metaphor of a house as a search environment, with different rooms in the house representing different user groups (e.g., children and adults) and different kinds of searching. Each room in the house had objects that could be manipulated to represent different aspects of a search. Animations were used to suggest the type of search, and icons were used to represent different dimensions of the classification system e.g., a globe to represent the geographical setting, a clock to represent the time dimension, and theater masks to represent the emotional experience provided by the books. Records retrieved were represented as a bookcase of books, and individual records were displayed as text in an image of an open book.

Develop Interfaces for Browsing

Most OPAC systems require the user to think up appropriate terms for searching. This is difficult if the user is not knowledgeable in the subject area. Moreover, few users know how to identify the appropriate Library of Congress subject heading to use. A browse interface reduces the user's cognitive load by requiring only that the user recognizes relevant concepts. Three main approaches have been proposed for an OPAC browse interface: browsing the classification system or the class numbers assigned to library items, browsing Library of Congress Subject Headings, and browsing a semantic network of associated terms.

Class number browsing makes use of the principle that books on similar topics are assigned the same or neighboring class numbers. Users take advantage of this when they browse the library shelves. Class number browsing on the OPAC provides an online equivalent of shelf browsing—especially if the books' table of contents are available online for scanning. OPAC records can be displayed in

class number order to facilitate such browsing. Beheshti^[35] proposed using object-oriented graphical interfaces with images of books representing bibliographic records on the OPAC screen. Book titles can be superimposed on the spines of the book images, and these can be arranged by class number on the image of a bookshelf. If the classification system uses a hierarchical notation (e.g., the Dewey decimal classification system), the user will be able to broaden or narrow a search by using a shorter or longer class number and to zoom in on the detailed class number for a specific subject. For the Library of Congress classification system, which uses an enumerative notation, Huestis^[36] has formulated an automatic method of identifying ranges of class numbers.

Some writers have proposed making the Library of Congress Subject Headings thesaurus available online for users to browse. Subject headings have broader terms and narrower terms, as well as several levels of subdivisions that can be browsed hierarchically. However, the list of subject headings and subdivisions for some subject areas may be too extensive to browse easily. Allen^[37] and Massicottee^[38] have proposed ways of reducing the length of subject heading displays by replacing many headings with broad conceptual categories and summarizing all headings beginning with the same initial word or phrase with one line containing just that word or phrase followed by an asterisk to indicate that the line can be expanded.

The Library of Congress Subject Headings can be further enhanced with a network of associated terms to form a rich semantic network. Associations between terms can be based on the co-occurrence of two terms in the same bibliographic record. Associations suggested by Bates^[39] include title keywords with the assigned subject headings, two subject headings assigned to the same book, subject headings and the class number label (taken from the classification system), as well as two words in the same title. Such an enhanced thesaurus or semantic net increases the chances of the user's initial terms matching one or more terms in the system and allows the user to explore a rich network of links and associations.^[39]

Lin^[40] reviewed various ways of displaying a semantic network on a browse screen: hierarchical displays, network displays with links and nodes, scatter displays (graphical dotted images produced by mapping high-dimensional data to a 2-D visual space), and map displays which apply the geographical map metaphor to information space.

Web interfaces provide a natural way of navigating and browsing a semantic network using hypertext links (hyperlinks). For example, in most Web OPAC interfaces, bibliographic fields that are displayed in the search result screen can be clicked on by using a mouse device. Clicking on a subject heading displayed in a bibliographic record automatically sends a search request to the OPAC system to search for other records containing the specific subject heading.

Enhance Catalog Records with More Subject and Table of Contents Information

Catalog records can be enhanced with more subject information in a number of ways:^[41–44]

- Include the book's table of contents in the record.
- Include selected terms from the back-of-book index.
- Include in the record terms from the Library of Congress Subject Headings that are related to the assigned subject headings and terms in the classification schedule that correspond to the assigned class number.

Enhancing the catalog records in the above ways will increase the probability of retrieving relevant records and reduce the number of searches that retrieve no records. It will also allow the user to use more specific terms in a search rather than the possibly broader subject descriptors used in the subject fields.

The disadvantage of enhancing catalog records in these ways is that more nonrelevant records will be retrieved and it is much more likely for a search to retrieve too many records for the user to scan.^[45,46] This will place a heavier burden on the user to know how to narrow a search when too many records are retrieved.

Traditionally, fiction books are not assigned subject descriptors in online catalogs. However, fiction books constitute the major proportion of loans in public libraries, and effort is now being made to assign subject headings also to fiction materials.^[47]

Provide Query Expansion and Query Formulation Support

OPAC users need more help with query expansion to identify broader, narrower, and related terms to use in a search, and with query formulation to formulate a Boolean query in the search language of the system. A number of prototype OPAC systems have explored the use of an online Library of Congress Subject Headings or some other thesaurus or semantic network to help users identify alternative search terms and controlled subject descriptors to use.^[48] This has been shown to be useful and effective.

Drabenstott et al.^[49–54] developed a prototype OPAC system that matched the user's query terms with entries in the Library of Congress Subject Headings and displayed the exact and partial matches for the user to select. If the user's terms matched a "see" reference, this was automatically replaced with the authorized subject heading. The user could then browse the thesaurus structure to view broader, narrower, and related subject headings as well as the subdivisions.

Poo and Khoo et al.^[55] in a prototype expert intermediary interface called the E-referencer used a knowledge base of associations between title keywords and subject headings. The keyword-subject heading associations were

derived by analyzing several years of catalog records. For each title keyword, all the subject headings associated with it (i.e., assigned to titles containing the keyword) were identified and assigned a score equal to the number of times the heading was assigned. The raw scores were then normalized by dividing by the highest score (the score obtained by the most frequent subject heading). The normalized scores were used to represent the strength of the association between the title keywords and subject headings. This knowledge base was then used to identify the subject headings that were most highly associated with the users' query terms.

Larson^[56,57] and Micco and Pop^[58] have proposed an indirect way of query expansion by clustering records in the library database by the class numbers assigned to the records. The title keywords and subject headings of all the records in each cluster are then used as index terms to the cluster. A keyword search would retrieve not just the records containing the keyword but all other records belonging to the same cluster as the retrieved records. A list of retrieved clusters, with their class number and some descriptive phrase, can be displayed for the user to select.

The OPAC interface can also incorporate some degree of natural language processing to allow users to express their information need in natural language and have it converted it automatically to a Boolean query. ALEXDOC^[59] was one natural language retrieval front end that performed linguistic analysis to match the user query with terms in the thesaurus and constructed a Boolean search statement using a set of transformation rules. Researchers have developed other automatic methods for constructing Boolean queries from natural language statements (e.g., Salton).^[60]

Provide Non-Boolean Best-Match Search Capability

Information retrieval researchers have advocated a "best-match" retrieval approach with relevancy ranking for the OPAC system. In such a system, records containing some or all of the user's terms are retrieved, and relevancy ranking is performed to display the records in decreasing order of probable relevance—with the records that most closely match the user's query being shown first. A major advantage of best-match systems is that natural language queries can be processed by the system and users need not formulate Boolean queries.

Best-match retrieval approaches include the vector-space model and the probabilistic model^[61] and are commonly used in Web search engines and full-text retrieval systems. The Okapi system^[62–64] is a well-developed experimental OPAC system that used a probabilistic best-match approach. Relevancy ranking is available in the Library of Congress OPAC system (URL <http://catalog.loc.gov/>) but is still generally uncommon in OPAC systems. Extended Boolean retrieval models that combine the

strengths of Boolean retrieval with best-match relevancy ranking have also been proposed.^[65–67]

Best-match retrieval requires different indexing structures and search mechanisms in the back end of the OPAC system than those used for Boolean retrieval. An alternative to using best-match search engines in the OPAC system is to incorporate some relevancy ranking capabilities in the OPAC front end residing on the user's desktop computer or in a middleware or metasearch engine that sits between the OPAC server and the user's computer. This can then behave as an intelligent agent to retrieve a large number of records from multiple OPAC servers and perform relevancy ranking on the records retrieved.^[55,60,66,68–70]

Incorporate Search Heuristics and Relevance Feedback Capability

Hildreth^[24] pointed out that “to optimize retrieval results in subject searching, more than one search approach may have to be employed in the overall search strategy.... Conventional information retrieval systems place the burden on the user to reformulate and re-enter searches until satisfactory results are obtained.” Cherry^[5] analyzed zero-hit subject field searches and found that converting the queries to other search forms such as keyword subject, keyword title or title searches would have obtained useful hits in 71% of the cases. An OPAC system can use automated search algorithms to reformulate the user's search query and refine the search criteria to improve the search results.

Cheng^[71] described a front end to the OPAC system at the University of Illinois, Urbana–Champaign, which executed a sequence of strategies to help the user improve the search results. When an initial search did not find a subject heading, the front end performed a sequence of modifications on the search string, including adding a truncation sign, displaying alphabetically similar headings, separating the words and searching by using the Boolean AND, and finally searching for the words in the title. If the title search retrieved a relevant record, the system extracts the first subject heading from the record and continued the subject search with that heading.

Automated search heuristics can also be used to simulate relevancy ranking. The E-Referencer system^[55,68] first formulated a narrow search to retrieve and display the most relevant records. Broadening strategies were applied gradually to retrieve additional records, which were appended to the end of the display. Because the records retrieved by the broadening strategies were less likely to be relevant than those retrieved by the initial search, the result is a list of records roughly in order of probable relevance.

Search algorithms can also be used to perform relevance feedback: the user can indicate which of the retrieved records are relevant, and an automatic procedure

can attempt to retrieve other relevant records by analyzing the records already retrieved to extract appropriate terms to include in a new search.^[24,72]

The CITE system^[73] performed a frequency analysis of the subject headings that occurred in the records that the user indicated to be relevant. It then displayed a ranked list of the subject headings for the user's selection. Classification numbers from the relevant records were then used together with the selected headings in a best match search.

In the Okapi system,^[63,74] the automatic query expansion facility took the subject headings and classification numbers from records chosen by the user and assigned each a weight based on the number of chosen records in which they appeared. Later versions of Okapi made use of interactive query reformulation where users can select the subject headings to use in a new search. The researchers found that fewer users took up query reformulation than expected and concluded that a better balance between automatic and interactive query reformulation had to be designed.^[75,76]

Incorporate Search Trees and Knowledge-Based Techniques

Although using a fixed sequence of search heuristics and query reformulation procedures have been shown to improve the search effectiveness, more flexible and sophisticated methods for selecting appropriate search strategies in response to different situations might work better than a fixed sequence of heuristics. Expert systems or knowledge-based systems have been proposed for online searching. An expert system that embodies within it the knowledge and skills of a librarian or “search intermediary” for carrying out online bibliographic searches is called an expert intermediary system.

Several researchers have attempted to apply knowledge-based techniques to information retrieval. Gauch^[77] and Ford^[78] surveyed some of the more well-known systems. Most of these have focused on abstracts and full-text databases, rather than library OPACs. They have also focused on the selection of query terms from a thesaurus or semantic net representing the knowledge base. Chen^[79] and Khoo^[80] present designs of expert intermediary systems that focus on search strategies and rules for selecting them.

Chen's system^[81,82] was the most ambitious expert intermediary system developed for OPAC subject searching, with many search strategies and knowledge bases. However, the prototype was applied to a very small database and narrow domain, and it is not clear whether it can be scaled up easily to a real library database.

Drabenstott et al.^[50–53] has developed a prototype OPAC system that uses search trees or decision trees that represent how experienced librarians might select a search strategy and formulate a search statement. The decision tree was represented as a flowchart and was developed on

the basis of an analysis of user queries captured in OPAC transaction logs.

The E-Referencer^[55,68-70] was a prototype expert intermediary system for searching OPACs on the Web. It was implemented as a proxy server that mediated the interaction between the user and Boolean OPAC servers. It processed the user's natural language query, mapped the query words to Library of Congress subject headings, selected a suitable search strategy, and formulated an appropriate search statement to send to the library system. Based on the user's relevance feedback on the search results, it further selected a strategy for refining the search. The knowledge incorporated in the E-Referencer comprised:

- A conceptual knowledge base that mapped free-text keywords to subject headings.
- Search strategies coded in the system.
- Initial search strategies for converting the user's natural language query to a Boolean query.
- Reformulation strategies for refining a search, including broadening strategies, narrowing strategies, and relevance feedback strategies.
- Rules for selecting an appropriate search strategy in the form of a decision tree.

MULTIPLE LIBRARY OPACs SEARCH

With the advent of Internet and the high-speed delivery of information via efficient networking infrastructure, multilibrary OPAC and electronic databases, search has now become a reality and is becoming a necessity in the offering of library services. In Poo,^[83] Poo and Khoo discuss the problems with Information Overload, a phenomenon brought about through the globalization of information via the Internet and demonstrate how various state-of-the-art technologies can be applied to enhance user's experience in multicatalog and electronic database search.

CONCLUSION

Users have many kinds of problems performing subject searches in OPAC systems. Typical users do not have the range of knowledge and skills needed for effective subject searching. This entry has surveyed possible improvements that can be made to OPAC system design.

With developments in Internet and Web browser technologies, many of the proposed improvements can be instituted without major changes to the OPAC back end system. Changes can easily be made in the design of the web pages used as an interface to the OPAC. Dynamic HTML, Javascript, and Java applets can be used in Web OPAC interfaces to provide users with more assistance and to implement more interactive direct manipulation

features. Improvements that require access to a knowledge base or more processing power can be implemented in a middleware program (metasearch engine or intelligent agent) that sits between the user's computer and the OPAC server. The middleware can be implemented as Java servlets that use the Z39.50 Information Retrieval protocol or the internet HTTP protocol to communicate with the OPAC server. Solutions using Java applets and Java servlets have been implemented in a number of systems.^[55,69,83,84]

OPAC interfaces are playing increasingly expanded roles. They now provide access not just to records of books and journals held by a library but also to multiple library systems, to full-text documents and journal articles, and to databases and other resources on the Internet. OPAC interfaces are increasingly becoming digital library interfaces and even Web portals, providing a window to the world of information. This presents new challenges for developing OPAC interfaces for subject searching.

Online Library Instruction

Beth Evans

Library, Brooklyn College, City University of New York, Brooklyn, New York, U.S.A.

Abstract

Online library instruction, or instruction in information skills delivered over the Internet, varies in its content, levels of technical complexity and intended audiences. Public libraries and special libraries, academic libraries and school libraries, graduate schools of library and information studies, library organizations, commercial vendors, and individuals all provide library instruction in an electronic environment. Delivering library instruction through the Internet is a new approach for educating learners and researchers using technology. It comes at a time of an increasing desire for librarians to educate themselves and their users and follows a history of librarians applying technology in education.

INTRODUCTION

A child studying in the Denver Public Library learns how to navigate through the online public access catalog using a specially designed interface for children.^[1–3] A lawyer at the Miami office of a national firm is referred to information about electronic resources on the library website by the law librarian at the firm.^[4] A library school student takes an online distance education class in “Managing Change in Information Environments” through the University of Pittsburgh FastTrack MLIS program using a computer at a cybercafe in Clarksburg, West Virginia.^[5] Library paraprofessionals at Northwestern University Libraries, once trained on the job with a video on handling library materials, now acquire new skills on their own with a self-paced, Web-based tutorial.^[6]

Online library instruction, or instruction in information skills delivered over the Internet, varies in its content, levels of technical complexity and intended audiences. Public libraries and special libraries, academic libraries and school libraries, graduate schools of library and information studies, library organizations, commercial vendors, and individuals all provide library instruction in an electronic environment. Delivering library instruction through the Internet is a new approach for educating learners and researchers using technology. It comes at a time of an increasing desire for librarians to educate themselves and their users and follows a history of librarians applying technology in education.

HISTORY

The Need for the Teaching Librarian

Three major American library associations have recently crafted mission statements identifying ongoing education

and professional development as critical for practicing professional librarians.^[7–11] Embedded in each of these statements is the understanding that librarians who upgrade their skills are better equipped to further the information education of their constituents. Increasingly, librarians are expected to be both learners and teachers. They are expected to understand different learning theories and adapt them to the different learning styles of students.^[12,13] The purpose, according to theorists, is to position librarians to make lifelong learners of information seekers.^[14] Fig. 1 shows an exercise from a Web-training tutorial.

The Emergence of Distance Education

Distance education allows learners to become educated in many disciplines where barriers of time and place may have once prevented them from accessing instruction.^[16,17] Early distance education was often delivered through correspondence courses mailed to students and extension courses taught by faculty who traveled to remote sites.^[18–20] Technology has expanded the options in delivering distance education. Although higher education may have been slow to adapt to the new methodologies,^[21] according to the National Center for Education Statistics, one third of colleges and universities in the United States offered distance learning courses in 1998, and 20% of the schools not offering distance education courses at the time had plans to do so within the following three years.^[22] Furthermore, if Gary Smith is correct that degrees offered for online study are recognized to be of equal value to degrees offered for a traditional course of study,^[23] a major social, political, and economic barrier to students choosing online learning will be removed.

Though the Open University in the United Kingdom is often cited as the model institution offering an entire curriculum remotely since 1970,^[24] colleges in the United

Fig. 1 An exercise from the Learning Café, an online information literacy tutorial. Tutorial exercises that allow for interactivity on a Web site are believed to increase student learning.(From Scarlatos.)^[15]

States have offered technologically facilitated courses since the beginning of the twentieth century. Technologies that have enabled distance learning around the world have included standard radio and television transmission; microwave; cable; open circuit; closed circuit, and satellite transmission; teletext; telephone; audio conferencing; facsimile; videodisc; slow scan video; sideband FM transmission; and Instructional Television Fixed Services. Distance education programs have partnered universities with each other and with broadcasting networks, foundations, and corporations.^[25–28]

Online Education as Distance Education

Linda Harasim makes the point that

[o]nline education is not the same as distance education, although it shares some of the same attributes. Both are any place, any time, and largely text-based. However, the critical differentiating factor is that online education is fundamentally a group communication phenomenon. In this respect, it is far closer to face-to-face seminar-type courses.^[29]

Whether the current examples of online library instruction conform to Harasim's model is a reflection of the evolving thinking about the purpose and method of library

instruction, the varied audiences targeted, the content delivered, and the methods of delivery employed.

SETTING THE STAGE FOR ONLINE LIBRARY INSTRUCTION

Predictors and Predecessors

Looking to the future of libraries and librarians in the last two decades of the twentieth century, a number of writers foretell of the lessening of the importance of the physical library collection, the increasing availability of electronic resources, and the subsequent decreasing need for librarians to work in a dedicated, physical location. F. Wilfrid Lancaster describes libraries as becoming “disembodied,” necessitating that in order “[t]o survive, the librarians must get out of the library.”^[30] Carolyn Dusenbury and Barbara G. Pease consider the lessening importance of having a physically present librarian in a physical library with particular respect to library instruction:

Can we continue to expect users to come to our place at our pre-set time in order to learn what they need to learn? Can we expect all users to be equally motivated or equally ready to learn at the same time? These questions combined with staff and budget shortages are causing careful re-examination of how resources are deployed and how effective current programs are.^[31]

The Library and the Early Days of Distance Education

Librarians have long been sensitive to the desire of students to learn research skills at their own convenience. Reference desks were established in libraries to provide point-of-need research assistance.^[32–34] Similarly, an essential concept in distance learning is timing delivery to connect with the learner at the moment of need. The early efforts of libraries to use technology to reach and assist researchers studying on their own predate the widespread use of the Internet. In the 1980s and early 1990s, libraries saw video and satellite television as ways to instruct without an instructor being present.^[35] Programs such as Elginet in Illinois,^[36] the Library Video Network in Maryland and, nationally,^[37] the Global Library Project at the Library of Congress^[38–41] and the Library and Information Science Distance Education Consortium^[42] developed and delivered staff and pre-professional training videos and information programming to the public. Fig. 2 shows the Library and Information Science Education Consortium website.

Computer Assisted Instruction (CAI) in Libraries Prior to the Internet

The computer-assisted demonstration

Librarians began to use the computer to assist with instruction as personal computers became more ubiquitous

in libraries and on college campuses during the 1980s. At the same time as the growth in the availability of computers in the library, there was an increase in library reliance on online searching of remote subscription databases. Electronic classrooms with multiple computers available for all students were yet to come, but in the 1980s librarian instructors used computers with projection systems for live demonstrations of online resources to catch the attention of students and to give them a realistic sense of an online searching environment.^[43] Moreover, librarians continue to teach with computer-assisted demonstrations using laptops and portable projection systems when the computer classroom in their library may not be available and they work with students in noncomputer equipped classrooms outside the library.^[44]

Live assistance and hand-on, computer-based learning

The computer, as a tool to assist with learning information skills, moved out of the hands of the instructor and into the hands of the students when libraries gained access to or built computer classrooms. Librarians teaching in person instructed students in practical skills, particularly in online searching.^[45] Linda Friend describes the new role academic librarians were able to play as consultants for their patrons who were paying for personal accounts on online systems. These remote users were working without detailed manuals and were likely to need help choosing

Fig. 2 Web site for the Library and Information Science Distance Education Consortium. Before wide-spread use of the Web, consortia fostered distance learning in librarianship through televised workshops.(From Barron.)^[42]

search terms and constructing a search. Librarians provided initial patron training sessions in person and were then on call to do follow-up troubleshooting for students working at remote locations.^[46] In addition to librarians giving live, hands-on instruction in searching vendor-provided databases, librarians also used the electronic library classrooms to instruct in how to use the online library catalog, or online public access catalogs (OPAC).^[47] The OPAC has typically been a library-created database and not a subscription product available from a vendor. Requiring no per-search or connection-time fees, the OPAC was often the first publically available, end-user electronic resource in a library and an important candidate for classroom exploration.

Tutorials for independent learning

With the increasing presence of the personal computer in academic libraries, librarians began to develop computer-assisted instruction software to meet their local training needs. Instruction continued to focus on online searching as one content area. Nancy Fjällbrant observes the affinity between method and content in discussing CAI tutorials developed to teach online searching: “[o]nline information retrieval is an interaction dialogue between the user and the host computer. It is, therefore, hardly surprising that computer-based learning packages have been developed for online training purposes.”^[48] Tutorials for online searching instruction primarily targeted graduate students and faculty. Nonetheless, in addition to developing CAI for these advanced researchers, academic librarians created CAI applications to provide basic library instruction for large numbers of undergraduate students.

Librarians designing tutorials for stand-alone computers often used Hypercard and Macromedia’s Authorware and Director. Instruction librarians who did not see themselves as technologically sophisticated praised these tools for their simplicity to learn and use.^[49] Modules were developed and saved on CD-ROMs that could be mounted on individual library or campus lab computers,^[50,51] set up in information kiosks,^[52] or offered to students to use at remote sites. Andrew Cox, writing in 1997 with a historical perspective on pre-Internet CAI delivery, points out an advantage of students learning from the nonnetworked CAI modules. When students are working in the Web-environment, they can easily click their way out of their focused task. Students using tutorials in the stand-alone environment, however, are not as easily sidetracked.^[53] Nonetheless, despite the possible drawbacks of delivering instruction through the Internet, as libraries began to go online, Web-delivered instruction began to replace CAI delivered on stand-alone workstations and on local area networks (LANs) restricted to the library or campus.

THE INTERNET, LIBRARIES AND ONLINE LEARNING

The Case for CAI

Arguments in favor of creating computer-based instruction have withstood the migration of delivery from stand-alone computers and LANs to delivery over the Internet. Supporters of CAI reason that student use of the computer-based instruction frees up staff time and offers a consistent set of material.^[50,51] Additionally, when learning with live instruction, students are limited to learning from one individual. A CAI tool usually reflects the talent and ideas of a number of creators, and students gain from the expertise of all. Furthermore, when a librarian is not available to assist them, students may use a computer-learning module at their own convenience and work at their own pace. Working with a computer application provides students with a nonjudgmental environment where they may be more comfortable venturing with answers to questions posed or reviewing material taught early on in the tutorial. In addition, because CAI can be used outside of class, instructors do not need to give up any of their teaching time to allow for library instruction. Lastly, computer-based instruction can also reach upper-level transfer students who may have missed the standard library instruction offered in conjunction with a freshman class.^[54–58] The many benefits of CAI and the increasing availability of Internet access have encouraged librarians to develop instructional tools to work in a number of teaching situations online.

Instructional Opportunities for Online Library Instruction

The advent of World Wide Web browsers has offered libraries new ways to instruct their remote users and the ability to reach more users than they can with stand-alone, CD-ROM tutorials. Online library instruction may be designed to orient users to a physical library or a library website through a virtual tour. The online instruction may focus on a single library tool such as an online public access catalog or on a vendor-provided database. It may provide general information literacy skills, focus on computer skills, teach research skills in the context of a given course, or deliver a full curriculum in library and information studies. The intended audience for online library instruction may be the public served by a single library or library system, K–12 students at a school, undergraduate and graduate students, faculty and staff at a college or university, library school students, working professionals in any field, librarians and library staff, individuals interested in upgrading their technology skills, and Internet surfers who may chance upon the website of a library providing instruction.

The virtual tour

Web-based information delivery has allowed many library services to be offered remotely. Consequently, researchers often may feel no need to visit the physical library. Librarians working with these remote patrons have often been eager to put a face on their virtual presence, or they have wanted to prepare visitors for what to expect before they visit an actual library, or they have created virtual libraries that have no physical equivalent as an access point to electronic information. Library virtual tours have been developed that make use of a range of Web technologies and give the distant user a sense of being in a physical place. The Stephens-Burnett Library at Carson-Newman College in Tennessee includes a virtual library tour module as part of a four-part instruction package. The virtual tour includes still images of each floor of the library and text descriptions.^[54,55] The Texas Agricultural and Mechanical University Evans Library Educational Media Services Department used Spin Panorama to update its original virtual library tour of still photographs and give a more realistic view of the six floors of their library annex.^[59-61] Using Macromedia Flash, librarians at the Baruch College of the City University of New York have created a virtual tour of the Newman Library with music and text available in nine languages.^[62,63] Jeff Bobicki's Libtech, a virtual library in the Active World Librarea, connects to Bobicki's writings on library technology topics and biographic information about authors through links embedded in book and face images.^[64-67] Each method of providing an online library tour orients information seekers so that they are better equipped to find what they need when they visit the physical library or continue to explore the virtual library website.

Focus on a single resource: the popular database and the OPAC

Librarians ponder if one day all library instruction will be built into every database they acquire for researchers. Successful, intuitive systems, it has been suggested, could eliminate the need for teaching librarians and serve as sufficient guides for doing research.^[68,69] Recognizing the limitations of database software design as it currently exists for the end users, both remote and in the library, librarians in many environments have developed online tutorials focused on heavily used, individual electronic resources. Institutions with large numbers of potential users, such as public universities or urban library systems, cannot give extensive live instruction in their online catalog or heavily used aggregated database to thousands of users, but they can reach any one of these patrons with an OPAC or a database tutorial.^[70-72] Database providers often provide help screens and tutorials to accompany the systems they design.^[73,74] But, as Anne Tubbs Prestamo

observes, users of electronic resources often do not use the built-in help links that come with most databases. Librarians who know the learning styles of their own clientele best may be the most appropriate instructors to design online help for these resources.^[72]

Teaching information literacy skills

Arguments against librarians investing time in developing CAI for individual resources include concerns that the interface and search options may change or the library may cancel its subscription to the product. Frequent changes in the appearance and functionality of information resources remain part of the impetus to design an information literacy approach to library education. Furthermore, advocates for teaching information literacy skills suggest that librarians move away from tool-based instruction and adopt a concept-based approach to library instruction instead.^[14] In designing CAI that teaches students how to use the online catalog and individual databases, librarians intended to package tool-based instruction and consequently free more of their time for concept-based instruction in the live classroom. Nonetheless, librarians have also developed online tutorials to deliver basic information literacy, or critical thinking skills. Nancy H. Dewald found, in 1999, that a majority of the online library tutorials noted by the ALA Library Instruction Round Table fell into this category of teaching general, information literacy skills.^[75]

Colleges and universities that traditionally offered in-person classes have begun to supplement their curricula with distance education courses to provide an extensive range of information literacy tutorials. Commercial online education providers, however, such as the e-global library of Jones International, have also offered tutorials in library research skills for those studying through an institution partnered with Jones and for individuals willing to pay for the service.^[76,77] Regardless of the provider, online information literacy skills tutorials are often modular with each module being made available as it is developed.^[78] Though not tied to the academic courses of study that students will choose for their majors, basic online library instruction at academic institutions is often embedded in freshman courses designed to ease the transition from high school to college. Basic library tutorials are included as part of English composition courses generally required of all college students.^[54,58,79,80]

Alternatively, librarians may develop basic library instruction modules without a guaranteed group of users in mind and seek out a small pilot group in one academic department when the online modules are ready to deliver.^[81] Additionally, developers may find that online information literacy modules are adopted and required by faculty in a range of courses soon after the library makes them broadly available. Although the tutorial designers may create instruction modules with a look and feel

designed for freshmen and sophomores, upper classmen are likely to use the tutorials and need to be considered as a potential audience in the design process.^[78] A library may also consider offering its basic library instruction tutorial with multiple interfaces to appeal to its various targeted audiences.^[82] Furthermore, a library may need to develop information literacy modules with varied content reflecting the developmental stages of student learning or a progression of skills.^[83,84]

Discipline-specific online library instruction

An information literacy, or basic library skills, approach to research education, though it seeks to serve the needs of many, may be found to fall short in helping learners with specific, deep, and complex research assignments. Consequently, library instruction, live and online, in the university, is thought to be most effective when tied to the research work required of students registered in discipline-specific classes. Course-related library tutorials have been developed for courses in business,^[85] criminal justice,^[82] engineering,^[86,87] chemistry,^[88] biology,^[89,90] modern languages,^[91] and Latin American studies^[92] as well as other disciplines.

Creating and successfully implementing course-related, Web-based instruction depends on cooperation between the library and college departments. A department may invite the campus library to develop a tool to assist with teaching research specific to a discipline.^[85,92] An advantage of course-related library instruction is that departments are likely to pool resources with the library and jointly seek funding to cover the cost of technologically enhanced learning tools.^[91] When developing course-related tutorials, the librarian typically will discuss their development and use with the classroom instructors who will be teaching the course prior to their delivery. When the classroom instructors are not familiar with the tools the library has created, the students, who are required to use the tools for problem solving in their classes, quickly become frustrated and see both their instructors and the library as falling short of adequately preparing them for their tasks.^[89]

Library instruction tied to courses presents opportunities for collaboration and sharing among students, faculty, and librarians. In the Learning Links Project, jointly run by the Spanish and Portuguese Department and the Scholarly Communications Center of the library at Rutgers University in New Jersey, graduate students in Spanish language and culture courses developed websites and prepared multimedia material that the undergraduates used in their own study.^[91] Students in a library media course at Georgia State University had an opportunity to do collaborative Web development online with a sister library in Toulouse, France.^[93] Additionally, librarians who develop course-related, online resources have something substantive to share with their colleagues in the library. A

librarian with responsibility for collection development in a particular subject area may rework, to suit his or her own instructional needs, a course-related tutorial developed by a colleague working in another discipline.^[82]

Online library instruction as a credit course

Many institutions have designed online library instruction to teach broadly applied information literacy skills or to support specifically focused college courses. Though these modules and tutorials may be connected with individual courses, the library content is adjunct to the course content. Learning the library content may contribute to the students' earning a grade but achieving these skills is not an end in itself. Colleges and universities do offer a number of examples of library instruction comprising the complete content of online, credit-bearing courses. Moreover, the examples of information-skills courses offered for credit at academic institutions often have in common interinstitutional ties or multidisciplinary content. In some situations, in order to make the creation of the tutorial worth the time and resources required, extensive application of the finished tool is required.

The Utah Academic Library Consortium currently supports a credit-bearing, information literacy tutorial Internet Navigator offered in 10 public and private colleges and universities throughout Utah.^[94] Fig. 3 shows the opening screen. Each participating school has independently selected the department that offers the course, has determined the amount of technical support needed, and has set tuition according to its own guidelines.^[95] Mercy College in New York State and Hasharon Distance College in Israel partnered to deliver an eight week, eight module course on research using the Internet. Students at Hasharon take the required course in their first semester, are encouraged to connect their research to what is needed for their other classes, and use the subscription online resources offered by the hosting college in the United States. The instructor of the course notes the special cultural challenges of teaching across national boundaries.^[96]

Interdisciplinary fields such as women's studies and area studies, or topics students develop that cross over discipline boundaries are challenging for both the classroom instructor and the librarian to teach and for students to research successfully. A brief, single session in the library is not adequate to introduce the major research tools from all the included disciplines. Nor is one individual instructor expert in the range of fields that may comprise an interdisciplinary topic. Consequently, interdisciplinary studies are good candidates for any method of library instruction that is not bounded by the constraint of a single session with a single instruction librarian in the library. Patricia J. Herron and Lily G. Griner have had an opportunity to teach a live, one credit research course in Latin American Studies and integrated a Web component, a noninteractive research guide, into

Fig. 3 The opening screen of the Utah Academic Library Consortium's Internet Navigator Tutorial. Library tutorials have been developed for use as credit-bearing courses implemented across a number of institutions.(From Hansen.)^[95]

the course they teach. The guide is extensive, reflecting the many fields upon which an interdisciplinary course draws. It was designed for students to print out and use in support of their other Latin American Studies courses.^[92]

Online library instruction in schools of library and information studies

Graduate programs in library education are increasingly providing opportunities for instructors to develop credit-bearing online courses in information skills. Thirty-six colleges and universities in 25 states in the United States and in Canada offer graduate students in library and information studies distance education opportunities.^[97] In 2001 the United States Institute of Museum and Library Services awarded two of seven grants to universities and colleges with projects designed to recruit and educate students in library and information science through distance education.^[98] Distance education programs in developing nations such as India and Thailand recognized the limited availability of computers and reached out to future librarians and information professionals with numerous study centers to provide online learning.^[99–101] The Open University in the United Kingdom, educating a more affluent population, has encouraged personal computer ownership since the late 1980s and facilitated online learning in all disciplines including library and information studies.^[102] The British Open University Library, once faulted for not opening its doors to part-time students,^[103] began

extending access to electronic resources to all students in the late 1990s.^[104,105] This access is invaluable to distance learners in information studies. Fig. 4 shows the website of the University of Pittsburgh online MLIS program.

Online instruction for librarian professional development

Practicing librarians and library support staff continue to need instruction in understanding, using, and instructing in standard library operations, new resources, and technology systems. Commercial providers may concentrate on marketing one or two library-specific training tools,^[106] offer a diverse listings of online tutorials in Internet research skills,^[107] or provide a full catalog of online training options for both library and specialized technology skills with broad applications within and outside a library setting.^[108,109] Library consortia and organizations also have offered practicing librarians online training.^[110–112] In the fall of 2001, the Illinois State Library launched LibraryU, a clearinghouse of free tutorials aimed primarily at library staff and administrators, but they are also of use to library users.^[113,114] The advantages of libraries turning to outside providers to provide on line training to upgrade the skills of their own professionals and staff are that training can be offered in an extensive range of topics and carefully targeted to the needs of selected individuals. For smaller libraries with limited staff and local talent, turning outside of their own institution is the only option for professional

development. Fig. 5 shows a Webpage from an online workshop for professional librarians.

Options in Technology for Online Library Instruction

In addition to taking advantage of the many opportunities to offer online library instruction to a wide-ranging audience, libraries have experimented with an array of technologies to deliver online library instruction. Often libraries will mix different forms of technology in order to meet the different levels of students' needs and to work more effectively within the technological limitations of the library. Central Queensland University in Australia, for example, offers tutorial modules through the Web, but gives each participating chemistry graduate student an introductory video on the broad topic of information access and two CD-ROMs on searching the OPAC and on general database search strategies.^[88]

The examples of online library instruction suggest that for online courses to be developed, librarians need to be skilled in their disciplines, adept in pedagogy, and in some situations able to negotiate the politics of passing a curriculum through a campus evaluation process. Furthermore, in order to design and deliver online library instruction in the Internet environment, librarians must be skilled in using a range of sophisticated and rapidly changing Internet-based technologies. Librarians have delivered online

library instruction that has succeeded on different levels of functionality. Static Web pages have evolved into interactive, multifunctional sites. Some faculty have used courseware software to deliver their course content, while others have embellished their sites with streaming video and audio. Students have come to interact online with the course website, their professor, and their classmates. With each technology they choose, librarians have looked to appeal to their learners and to be effective teachers.

Moving beyond the static web page to web site interaction

The earliest and simplest uses of Web technology for teaching have involved construction of websites of information embedded with hyperlinks to related information. Librarians have designed sites as guides to major disciplines or tied directly to individual courses. The sites may reflect a particular instructor's syllabus and library assignments and can double as handouts students may download and study for their courses. Librarians may also offer questions and quizzes on the websites and require students to print out and answer the questions in a traditional manner.^[92,115-117] As technological developments have given librarians the opportunity to reach a virtual community in a number of ways, advocates of using the Internet for instruction have urged librarians to think differently about how they can teach using a website. Bridget Loven and

Fig. 5 The Web site for Kovacs Consulting. Independent trainers offering Web-based workshops provide continuing education opportunities for practicing librarians. Source: Kovacs Consulting.^[107]

others stress that librarians “go beyond merely ‘digitizing’ handouts that already exist.”^[118] Websites designed for teaching should take advantage of technology that creates an environment as similar to a live situation as possible.

Although eager to create complex, technologically enhanced library instruction websites, libraries with a limited, in-house knowledge base may find themselves restricted to choosing only development tools that do not require extensive programming knowledge.^[71] Nonetheless, library administrators may also consider the need to create online instruction tools as an opportunity to expand on the skills of the librarians working in their institution,^[119] an occasion to hire nonlibrarians to do the development,^[50] or a chance to find partners with the necessary skills outside of the library. Such varied strategies have enabled libraries to be at the forefront of online instruction with cutting-edge technologies and also to use low-end technologies in new and ingenious ways. The library at the University of Tennessee at Knoxville found that by positioning itself to be the pilot project for streaming video on campus, the Telecommunications and Network Services unit of the college provided network and digitizing support for them to build a virtual library tour.^[120,121] Librarians at Bowling Green State University in Bowling Green, Ohio, conversely, used the simple ability to edit HTML source code from their Web-based catalog results screens, ready-made graphics, text written to appeal to students, and hyperlinks to create a Web-based tutorial for basic library instruction.^[70,122] Because of Internet

design restrictions on the Bowling Green campus, the authors looked for ways to achieve interactivity without the benefit of server-side scripts. Fig. 6 shows the opening screen of a virtual tour of the University of Tennessee Libraries. Fig. 7 shows the Bowling Green State University interactive tutorial FALCON.

Librarians have also used javascript programming and Macromedia Shockwave to enable their Web tutorials for interactive learning. Quizzes, such as those included in the tutorial for the library at the University of Nevada, Las Vegas,^[123] depend on javascript to allow students to answer multiple choice questions online. The information literacy tutorial (TILT) at the University of Texas at Austin^[124,125] and the Data Game at Colorado State University Libraries^[126] instruct in basic library skills with appealing and often humorous Shockwave presentations that move as the viewer clicks and makes choices. Including exercises that require the learner to be more than a passive reader is frequently recommended for good library tutorial design.^[75,127,128] Hyperlinking, scripting, and Shockwave have all given libraries different ways to integrate exercises into tutorial lessons and to include quizzes that require student input.

Reaching out to the online learner through electronic mail

Clicking on radio buttons and making selections from pull-down menus that are included as part of the exercises

Often a library tutorial may focus on a single resource and allow for interactivity without server or client-side scripting. Source: From Hunker.^[122]

or quizzes on an instructional website may give users of library tutorials a sense of active participation in the learning process. However, libraries have aimed to increase the interactive experience of online learning so that the student's interaction can be with the librarian instructor, or with other students, whenever possible, rather than only with a computer program or a website. Prior to the widespread use of graphical Web browsers, librarians reached out directly to potential users by delivering lessons in segments through e-mail. The librarians have instructed faculty, students, and staff, both affiliated and unaffiliated with their institutions. The e-mail instruction opened an opportunity for a direct, online conversation with an individual librarian.^[129-131] Even when libraries are able to offer instruction through the Web, as Sigrid Kelsey points out,

[t]he e-mail messages constitute a form of pro-active outreach; in contrast the web pages [are] a passive method of instruction largely dependent upon the participants' initiative to educate themselves.^[132]

Sending out instruction modules through e-mail may be seen as proactive, but once students have an invitation to e-mail an instruction librarian, the amount of student feedback may vary greatly. One librarian, who had established a mailing list of 109 interested readers for her seven-week sequence of lessons, received three e-mail queries from her students.^[132] Another librarian, however, running an online course with three graduate students in a school media program, sent out over 650 course-related e-mail messages, most dealing with technical issues.^[93] Academicians will often cite the large amount of e-mail that may be associated with running an online course to counter the belief that online education provides an opportunity to teach larger classes with no increase in instructor workload. Instructors have documented that running an online course and reading and answering student e-mail is more time consuming than running a traditional class.^[133] Teaching librarians in all capacities, who make themselves available to their students through e-mail, are as vulnerable to an unknown quantity of contact as instructors in other disciplines. Despite the potential for an overwhelming student response to an e-mail invitation offering support, however, librarians who offer their contact information to students and who also collect student e-mail addresses when they have the opportunity may find they have facilitated communication with individuals who might otherwise have held back from their instructor and remained reluctant to ask questions.

Expanding the connection with conferencing software, courseware, chat, and co-browsing

Telecommunications facilities allow the remote learner to communicate and to learn as part of a social process,

what Søren Nipper calls "the key element in the conceptual development of third generation models of distance learning."^[134] E-mail opened the first door of communication in the virtual classroom. Conferencing software and courseware have added features that enable the online classroom to mirror the physical classroom more fully. Conferencing or threaded discussion software allows for asynchronous discussion among students and instructors. An instructor posts text for consideration or poses a question and students respond. Each student's response is posted on a growing stream of responses to the initial posting. New topics engender new streams of responses.

Students may not be any more responsive as a group when their class includes a threaded discussion than they are when they sit in a live classroom. Consequently, instructors have a responsibility to keep students involved in an online threaded discussion.^[96] Faculty may have to cajole reluctant students to participate and require them to refer to the discussion content in their written assignments.^[24] As with physical classrooms, some students are more willing to participate than others. Conversely, students who may be reluctant to talk in a traditional classroom may be more comfortable and willingly express themselves in a written discussion setting.

Multifunction courseware packages such as TopClass,^[135] eCourse,^[136] WebCT,^[137] and Blackboard^[138] have expanded instruction possibilities for librarians offering course-integrated and credit-bearing instruction. The packages do not require the instructor to know hypertext mark-up language (HTML). They allow teachers to incorporate text documents and multimedia on their course sites, manage multiple courses, give online examinations, and monitor their students' achievement and grades. The software may provide an area for student biographies and images so that student working together virtually can attach faces to names of classmates. One application originally designed for business conferencing, Microsoft's Netmeeting, integrates a camera and audiobridge to allow online library instruction to include audio and visual connections in real time.^[18]

A number of courseware packages allow for chat or synchronous discussion in addition to threaded discussion forums.^[80,91] Chat, or software that allows typed conversation in realtime, is becoming increasingly popular with libraries of all types. Businesses and dot-com information services such as Webhelp^[139] use chat to provide real-time customer service and to answer a range of queries.^[140-142] Chat allows libraries to extend their reference services with point-of-need assistance and may be used to answer reference questions as well as to instruct.^[143-145] Chat can be useful for librarians running online classes. It enables them to set up online office hours and have real-time conversations with their remote learners. Fig. 8 shows a website^[145] where online chat can be used for communication.

Fig. 8 The Virtual Reference Desk (Library Systems and Services) of the Illinois-based Alliance Library System. Chat software allows librarians to provide round-the-clock reference assistance and help with research. Source: Alliance Library System.^[145]

Chat as a tool for classroom interaction is limited by the typing abilities of those communicating and the tendency of chat conversations to become disjointed. Furthermore, most libraries currently offering chat service do not have the capability to engage more than one user synchronously with a librarian and each other. An emerging Web technology that is likely to replace chat and eliminate the tendency of conversations to become fragmentary is Voice over Internet Protocol (VoIP). Using VoIP, teaching librarians and remote learners can speak to each other using their computers and avoid the typing required in chat.^[146–148] A drawback of VoIP is that it requires users on both ends to upgrade their computers with expensive peripheral hardware. It was not until chat software that did not require the client computer user to download any plug-ins became available that librarians began to set up chat services. Until the cost of having access to VoIP drops and the procedures for installing it are simplified, librarians are not likely to see it as practical for providing remote assistance and instruction.

Some software libraries have used, other than courseware, incorporates a chat function and may also allow for collaborative Web browsing. Collaborative Web browsing is useful for online library instruction when a librarian is working in real time with an individual student doing Internet research. The screen exchange allows the remote student to show the librarian unsuccessful strategies and results and the instructor to show effective alternative search techniques.^[149–151]

Assessment of Online Library Instruction

Usability, learning outcomes, and learner/instructor preferences

Recent studies of alternative teaching methods in libraries have found that students learn equally well with live instruction and with online tutorials.^[90,152,153] Such evidence may encourage libraries with shrinking resources to embark on a program of online instruction. Nonetheless, libraries and all institutions of learning that have a distance learning program in place need to evaluate individually if the way in which they are teaching is effective and should be continued.^[154,155] Teachers and administrators have to consider student feedback on the usefulness and appropriateness of the online instruction methodology in addition to examining evidence of student learning.^[85]

The Emerging Technologies in Instruction Committee of the Instruction Section of the Association of College Libraries provides a number of criteria libraries may use to evaluate their instructional tutorials.^[156] Early on in the process of designing a tutorial, libraries can evaluate how usable their online instruction is by organizing focus groups of testers who mirror their potential users.^[78] Measuring the usability of an online instructional tool, nonetheless, differs from measuring the effectiveness of the instruction carried within the tool. Whereas computer and telecommunications technology makes tracking the use of instructional material possible in ways that could not have

been done before so much information became available electronically,^[157] the use statistics gathered by the technology do not measure how much learning has taken place. In addition, testing students in course content in online learning situations presents unique challenges that would not exist in a live classroom where the student seen attending a course is the student who arrives for a test.^[96,158,159] Moreover, as Denis Madland and Marian A. Smith point out, with specific reference to library instruction, educators would like to know if the skills learned through a library tutorial administered early on in the college career of a student carry over and show up as ability in a student doing research in later semesters.^[160] The question, nonetheless, is a question that may be asked of all library instruction, online and in person.

Libraries may find that using online instruction meets their needs to reassign professional staff to other tasks, but online instruction may not meet all of the needs of the students who are asked to use the CAI as their primary tool of learning. Furthermore, online instruction may not meet all the needs or desired goals of the instructors. Both students and instructors may favor live contact with each other and doubt that electronic correspondence is the most efficient or effective way to communicate with each other. Students encountering all library tools virtually through a CAI module may look for opportunities to use the physical library collection,^[161] value anything they can take away in print from a session with an online tutorial,^[58,90] and give highest ratings to the time spent with a librarian in person when their lessons couple traditional and online learning.^[80] Moreover, in some situations, computer-based instruction may be contraindicated. Students in a freshman program at California State University at San Marcos were not confident in their computer skills. This weakness, coupled with difficult subject matter, inhibited learning.^[79] Additionally, according to one study, students tracked into online library instruction modules as an alternative to live instruction show a high rate of failure to complete the instruction as offered.^[153] In addition, student ownership of a personal computer has been found to impact on the ability of participants in a sequence of online library instruction to do well in the course.^[86] Colleges and universities requiring that students learn through CAI need to consider this imbalance in outcomes as they plan a campus computer infrastructure and, alternatively, debate requiring all incoming students to own or lease a personal computer.

Economic viability

In addition to determining if online instruction is an effective teaching tool, researchers and administrators are interested in assessing the economic value of developing online learning.^[162,163] Librarians may assert that online instruction saves money without giving specific evidence of the facts.^[56,153] V. Lonnie Lawson, however, did a cost

analysis of developing CAI for library tours in comparison to the cost of staffing live library orientation visits. The analysis showed that the high cost of investing in hardware can outweigh the cost-savings in staff time.^[164] Polley Ann McClure argues, additionally, that the use of technology in education is still in the research and development stage where the costs of development are a long way from being recovered.^[165] The desire of academic administrators to reuse, and, consequently, prorate the cost of packaged CAI, has led faculty to debate their institutions over ownership of online courses and has challenged visions of how much money could be made by colleges and universities offering instruction online.^[166] Moreover, designing and keeping current multiple versions of an instruction tool in order to reach learners who may be using older versions of browsers, have slow connections to the Internet, or have limited vision is an added expense of online instruction.^[78,84,120]

CONCLUSION

Individual institutions of education, including libraries, will find themselves reviewing programs of online education at other institutions as well as in their own settings to decide if such programs should be implemented, need to be redesigned, or are doing well to serve their purpose. Beyond the programmatic level, nonetheless, these same institutions and academicians everywhere are considering the place of online education in the greater philosophical framework of what is the fairest and best way for an individual to learn.^[167] Concurrent with the discussion about the overall value of online education, moreover, librarians have been engaged in an ongoing dialog to define themselves clearly as educators, rather than guardians or deliverers of information. Electronic resources and telecommunications connectivity have removed the content of libraries from the physical structures of these institutions. Traditional library users have gone into cyberspace seeking out information and taking it where they find it. Librarians who see that their users are turning to this new online setting, look for ways to continue to play a role in the information-seeking experience for these online adventurers, even as they continue to serve a physical public.^[168] Just as providing the information alone may never have been enough of a role to play to satisfy librarians who recognize that knowledge is more than information, developing ways to make information more understandable remains an important goal for librarians in an online environment. Whether they play this role in the design of the systems that deliver information, or stand aside from the information systems as partner-explorers with the information seekers, librarians continue to recognize the importance of researchers having successful experiences in their search for and assimilation of information. Remembering that the information seeker is the reason

that information is gathered has encouraged librarians to migrate with their users into the online environment. Providing online library instruction has enabled librarians to meet their users where they are working and make the connection from one physical space to another across the digital information sphere.

Online Public Access Catalogs (OPACs) [ELIS Classic]

Kevin Butterfield

Wolf Law Library, College of William and Mary, Williamsburg, Virginia, U.S.A.

Abstract

In one form or another, from a mental list in the mind of the librarian, to book catalogs, card indexes, and online information retrieval systems, some type of meta access has existed to guide library users through library collections. Over the last 40 years, these constructs of paper and wood evolved into Online Public Access Catalogs (OPACs). When the catalog shifted out of drawers and off of three by five cards to become a networked, universally accessible entity, its role in the library shifted as well. The OPAC competes with the World Wide Web, metadata registries, search engines, and more sophisticated database structures for attention. Amongst this assortment of access mechanisms, the purpose of the OPAC has become muddled. The OPAC has now become one information source among many and one of a number of portals for accessing library collections and beyond.

INTRODUCTION

As long as there have been libraries there have been catalogs. In one form or another, from a mental list in the mind of the librarian, to book catalogs, card indexes, and online information retrieval systems, some type of meta access has existed to guide library users through collections. Over the last 40 years, these constructs of paper and wood evolved into Online Public Access Catalogs (OPACs). When the catalog shifted out of drawers and off of three by five cards to become a networked, universally accessible entity, its role in the library shifted as well. The OPAC competes with the World Wide Web, metadata registries, search engines, and more sophisticated database structures for attention. Amongst this assortment of access mechanisms, the purpose of the OPAC has become muddled. The OPAC has now become one information source among many and one of a number of portals for accessing library collections and beyond.

HISTORICAL DEVELOPMENT

The OPAC is understood to be the technological device that replaced the card catalog. The card catalog had in turn replaced the book catalog form that preceded it. The widespread acceptance of the card catalog at the beginning of the twentieth century reflected a trend towards standardization. The format used by these card catalogs lasted well into the 1990s and represented the influence of mass production in libraries. Catalog cards were first written by hand in library script, then typed, and ultimately ordered from vendors or the Library of Congress. Later they were produced via bibliographic utilities such as OCLC using MARC records. Each change in turn marked a move

toward a more efficient means of record creation and maintenance.

The widespread acceptance of the online catalog in the early 1980s marked a trend toward experimentation in library catalog design.^[1] However, the card catalog still has a strong influence on how current OPACs have been developed. Current systems and usage patterns are historical artifacts of the library card catalog. The OPAC interfaces and usage patterns embody a history of assumptions made during the card era.^[2] At the time online catalogs were developed, the library catalog had reached a remarkable degree of standardization and stasis as a device. The standardization arose from the mass production of cards and from the cultural acceptance of the card catalog as an access device. Online catalogs upset that stasis, and it appears that the standardization enjoyed during the era of the card catalog will not return for some time.^[2]

Online catalogs did not develop during a crisis situation. There was no pressing need to find an alternative to the card catalog. The technological capability was there, so the attempt was made to apply the new technologies to the existing systems and routines. Thus OPACs were not brought about by a revolution, but by an evolution of need. A large catalyst in this development was the creation and widespread acceptance of MARC. Use of MARC led to lower cataloging production costs and a greater standardization of description. The first attempts at library automation revolved around card production, acquisitions, and serial control. As the data formerly typed by hand or printed onto three by five cards was encapsulated and transmitted via the MARC formats, libraries and bibliographic utilities began to amass archives of bibliographic records. A natural next step for these libraries was to experiment with making access to these archives available to librarians, libraries, and the public by adapting or

creating search interfaces and emerging computer and database technologies. Early library automation centered on using these records to computerize circulation functions. This tendency to apply new technology to existing systems and routines is a common response to technological advance. There seemed to be no overwhelming burden under which librarians and users toiled that motivated them to push for the development and implementation of online catalogs. Consequently, the OPAC was not expected to be a great improvement over previous catalog formats. It was simply seen as a better, faster way to realize desirable system and cost efficiencies.^[2]

The cost and capabilities of computer and communications technologies shaped the ability of libraries to realize these efficiencies, as well as drove the dominant trends in library automation over the last three decades.^[3] In the specific case of OPACs, four factors can be seen as necessary for their development and acceptance:^[2]

1. The technology had to be available.
2. It had to be available at a price that was perceived as cost efficient by potential purchasers.
3. The systems had to be acceptable to users with their specific needs.
4. Online catalogs had to mesh with the goals of the libraries that developed or purchased the system.

The requisite technology for the birth of online catalogs (other than the MARC record structure perhaps) developed outside the library profession. This parallels the current trend in digital library development. Digital libraries initially arose out of the engineering and computer science disciplines before catching on in libraries. In the early days of OPAC development, library collections still revolved around monographs and serials, in various physical formats. Automated library access to monographic holdings developed after automated access to journal literature in most fields was well established.^[4] Many of the design features of the prototype online catalog systems, however, did not mimic the automated systems for access to journal articles.

The card catalog remains as the most influential parent of online catalogs and reinforces the evolutionary nature of their development. Online databases of journal articles, for example, did not emulate printed abstracts and indexing tools to the extent that early online catalogs emulated the printed card catalogs.^[2] This may have been an outgrowth of the fact that the same MARC record used to produce a catalog card was being used to create an on-screen display. Libraries did not switch en masse from card catalogs to OPACs. Large bibliographic utilities such as OCLC were still producing cards for libraries during this transition period. As a result, there was no immediate or revolutionary change in the basic record structure. It still had to play a dual role.

The development of Integrated Library Systems (ILS) and OPACs has been a response to needs for efficient

production and maintenance workflows within libraries. Needs for efficient authority control, inventory tracking of serials, circulation, and acquisitions were among the initial reasons for their development. Most systems developed out of MARC-based cataloging systems or commercial online circulation systems. In both of these instances, automation of library staff functions came first. Efficient production and maintenance routines were the chief attraction of online catalogs, not enhanced access. To the extent that access was discussed, an increased number of access points to bibliographic records were stressed, rather than enhanced user access possibilities.^[2] Much of this can be traced to the relative lack of search engine and interface design development at the time, but it also demonstrates the continued influence of the card catalog paradigm.

Although several academic libraries offered enhanced keyword searching early in OPAC development, it was not until the advent of the World Wide Web that we see real pressure from users to develop more sophisticated search and display mechanisms for OPACs. As the field of interface design began to thrive and better, faster more efficient search mechanisms became standard on the Internet and within commercial databases, the pressure to develop more effective services to users of OPACs grew. The World Wide Web and the perceived universal access to content it provides have raised expectations for OPAC interface design.

The imagined production efficiencies hoped for from ILS and OPACs were within the library as an institution, not efficiencies to be realized by the users of information systems. Initially, online catalogs were much more attractive to libraries and librarians than they were to users.^[2] In terms of automating arduous tasks and maintaining tighter bibliographic control, the systems were a boon to libraries. Unfortunately interface design at the time was not as sophisticated an area as today. This resulted in often-difficult interactions with the catalog as users attempted to grasp the new technology.

Online catalog development initially was supported by underfunded institutions (e.g., libraries) and the systems needed to be designed for a broad, untrained user population. Database and user interface design were not, then, traditionally part of the librarians experience. This was definitely the case during these early days. These two facts may explain why online catalogs were not on the leading edge of bibliographic storage and retrieval development and reflect the evolutionary, rather than a revolutionary, nature of their development.^[2] These systems were designed not to replace, but to enhance and continue preexisting practice.

There were three major types of OPAC systems developing during these early years: in-house, consortium, and package or turnkey systems.^[5] Of the pioneering in-house systems, the Library Control System (LCS) of the Ohio State University Libraries is perhaps the best known. Developed by IBM for the university in the late 1960s, it

developed from a circulation system to an online catalog. The LCS planners did not envision patrons conducting their own searches at public terminals nor did they plan on replacing the card catalog with LCS. Nevertheless, both of these things came to pass.

Notable milestones introduced by LCS in 1978 included the ability to store and display full bibliographic records, the provision of subject access to records, and the ability to browse through subject heading lists.^[5] Other pioneering in-house systems were Northwestern University's Northwestern Online Total Integrated System (NOTIS) and the Virginia Tech Library System (VTLS).

Libraries and library consortia that have designed and developed online catalogs locally to provide access to their databases of MARC records represent another type of online catalog development. What sets these online catalogs apart from those such as LCS and NOTIS is their radical departure from the card catalog as the model for online searching. The database structure and search methods of these catalogs were modeled largely after commercial information retrieval systems such as DIA-LOG and BRS. The challenge for these online catalogs was not merely to apply the models used by these information retrieval systems but to also preserve the traditional functions of the catalog and to produce a retrieval system that could be used by novices without assistance.^[5] Dartmouth College Library developed an end-user, self-explanatory, user interface to the BRS retrieval system as their online catalog in the early 1980s by creating a database using Dartmouth's OCLC transaction tapes. These MARC records were converted to BRS's internal record format. The project was innovative in its interface design goals and it uses of a record structure other than MARC.

One of the more significant consortial endeavors was begun in 1977 by the University of California system. Dubbed MELVYL, the purpose of the catalog was to make it possible to use the separate collections of the university's libraries as a single collection or to allow a user at any campus to access the collection at any other campus. Since some of the UC libraries used OCLC and others used RLIN, MELVYL became the first catalog to successfully merge OCLC and RLIN records into a single database. The prototype version went operational in 1981. As a public-access retrieval system, MELVYL was innovative in that it had a file structure that supported keyword access and Boolean queries, a patron interface that included two user-selectable dialog modes (menu-guided and command language) and an extensive "help" facility.^[5]

During the 1970s commercial vendors began to replace large university libraries as the principal developers of computer-based library systems.^[3] Among the reasons were libraries' lack of funding and research and development staffing. Commercial vendors were able to fund development more consistently; however, they did not always understand the access needs of patrons. These were

more inventory control systems with a searchable front end for the public than true information retrieval systems. Early online systems evolved according to the hardware and software systems of the era. Those that ran on proprietary operating systems and hardware fell away replaced by those that ran on operating systems thought of as industry standards.^[6] These turnkey systems were implemented in libraries often with mixed results.

The economic and technical realities of the 1980s favored increased autonomy and local library responsibility.^[3] A reaction to the economies of scale of the online technologies developed. In the 1980s administrators tried to regain much of the control over their own operations and decision making that they gave up to the networks in the 1970s.^[3] Many institutions of higher education were getting out of the systems design, development, and support business.^[2] Libraries began either purchasing entire systems from vendors or assembling ILS modules from several different vendors to create systems that fit their needs.

During the 1990s, integrated systems design became the exclusive domain of vendors. However, libraries and universities began exploring a tangential subject, that of digital library development. With the explosion of the World Wide Web in the mid-1990s, many information retrieval systems and search engines were developed to locate, organize, and retrieve information on the Web. The OPACs, as information retrieval systems, were, in many cases, left behind. They are now beginning to find a role in this new information landscape. The interfaces for these early OPACs tended to be less user friendly than their paper-based predecessors. The strongest pressure for the adoption of online catalogs came not from users, but from library management. Again, a need to find better, faster ways to realize production and management efficiencies was a driving force. However, the more online catalogs are expected to perform the functions of inventory control, acquisitions, cataloging, and public access to the collection, the less likely it is that public users will have a system well designed for public use.^[7]

WHAT DO OPACs Do?

The OPAC serves as a public face on a library's ILS. The ILS controls the following functions:

- Circulation (keeping track of items checked out and by whom)
- Cataloging (keeping and offering access to materials)
- Acquisitions (acquiring new items and tracking payments for them)
- Serials (tracking periodicals, claiming missing, or nonreceived items and binding)
- The OPAC
- Interlibrary loan (cooperative sharing of library materials)

At the core of the majority of ILS is the MARC record. Although there are innovative systems using BRS/Dataware, SGML/XML, or SQL to reformat data, typically a MARC/AACR2r-based bibliographic record serves as the focal point for all functions. Order, serial check-in, item, and circulation records “hang” off of it. The bibliographic record acts as a surrogate for the item describing its provenance, content, and container. The ancillary records document financial transactions related to acquisition, continued maintenance, and usage by the public. The OPAC interface translates MARC tags within the records to display labels read more easily by the public (i.e., 100 becomes author, 650 becomes subject).

A great deal of effort must be put into translating tags into labels that make sense to nonlibrarians. Also, given the large number of tags in the typical MARC record, the OPAC displays can run quite long. This has given rise to the traditional brief record display in today’s OPAC. Typically one MARC tag generates one labeled field unless the system is instructed to collapse fields together. The library can, depending upon the ILS involved, control what gets displayed and in what order.

The OPACs will search MARC records by author, keyword, corporate name, class number, title, series author/title acronym, ISBN/ISSN/LCCN, subject heading keyword, and subject heading browse. In addition, most OPACs offer phrase and keyword searching. Keyword searching within OPACs has become problematic. Web search engines lead users to believe that OPACs provide deeper access to content than they actually do. The OPAC keyword search is dependent upon the keywords being used within the MARC record. A Web search engine keyword query may mine the full text of an item in an effort to locate the terms used. Since an OPAC consists of item surrogates rather than complete text, the results are not the same.

A review of OPAC search logs may reveal that users attempt to use the OPAC as if it were a Web search engine without knowledge of the classification and subject heading structures inherent in it. Content enhancement of the basic OPAC record would allow the user to take full advantage of the abilities of the basic OPAC, let alone the future incarnations. Addition of abstracts, table of contents, back of the book indexes, etc. would greatly enhance the search experience.

Advanced OPACs allow users to sort and save search results for export in specific data formats. Results can be imported into programs for creating bibliographies or databases. Increased access is also available to patrons for reviewing their circulation records or, in the case of academic libraries, print and retrieve reserve materials for classes.

The OPACs began as stand-alone systems unique to each library, much the same as card catalogs. If a user wished to search the online catalogs of multiple institutions, they would need to locate the catalogs for each and run their search repeatedly. As networking and the

Internet came to the fore, more and more OPACs became linked via academic, regional, and statewide consortia. Consortia allow for simultaneous searching across member catalogs or group specific types of libraries together in clusters depending upon the subjects they represent (law, theology, etc.) or their status (academic, public, etc.). Consortial catalogs allow users to search the catalogs of multiple institutions at once, collate the results, and request materials needed through cooperative borrowing arrangements. This allows users access to the combined catalogs of many public and academic libraries with enhanced borrowing functions. It facilitates cooperative collection development among the institutions involved, as they will now be able to see where collections overlap. This has become more prevalent as libraries shift from the paradigm of collecting materials “just in case they are needed” to providing access to materials “just in time.”

In addition, bibliographic utilities placed public search interfaces on their union catalogs. OCLC’s WorldCat and FirstSearch allow users to search across OCLC’s database and retrieve records for items throughout the world. The OCLC’s InterCat and CORC projects have extended the scope of the catalog beyond traditional media. Increasingly, recent journal holdings are being made available to libraries through aggregator databases. In a number of cases, vendors will hook the holdings of a particular journal title in their databases to the MARC record in the library’s OPAC, allowing users to find the print version of the text should the full text not be available in the vendor’s database.

These recent enhancements to OPACs have allowed them to serve as gateways or proxy servers to licensed databases. The ILS patron database can be used to verify that an individual has authorization to access the databases and ensure that the library functions within licensing agreements. Also, additional enhancements have allowed title-level access to aggregator databases, and hooks to holdings that allow reverse access as well. Methods have become available that allow users to jump directly from an OPACs bibliographic record to a Web site or electronic file, text, or journal. Use of the 856 MARC field as a linking technology or bridge between the catalog record and the item described has made this commonplace. It alters, significantly, definitions of the catalog. Now the catalog not only describes what the library owns, but also what the library potentially has access to. These developments illustrate a growing convergence of portal development and OPAC design. Through this portal-OPAC, the user gains access to resources and people far beyond what earlier, more traditional definitions of a catalog would allow.

HOW EFFECTIVE ARE OPACS?

Users come to the OPAC with a particular need for information. However, they tend to search the OPAC as if it

were a Web search engine. While various metadata schemes exist to provide more structure to Web-based information, they are not in widespread use. As successive generations of users, savvier at searching, come to expect natural language oriented, full text searching and retrieval, the OPACs interface and search capabilities begin to look dated in structure and potential. The surrogate record structure does not lend itself easily to that type of query. Most users are unaware of the catalog's structure and are unable to use it effectively.

OPACs depend on user expertise for reasonably successful operation. Given their increased use of search engines on the Web, it is hard for users to understand that they cannot find everything in the catalog by using their own vocabulary, as they would doing a Web search, but must use a precoordinated subject heading system that does not necessarily match their language usage or topical vocabulary. The OPACs are very bad at subject searching often due to poor authority control and subject heading assignment and the fact that increasingly students and the public attempt to search the OPAC as they would search with an Internet search engine. These two insufficiencies combine to provide poor search results. With international access to OPACs on the Web, automation in multilingual and multiscript environments becomes important. Some vendors support this, but not all.

There appears to be a need to break the public pieces of the ILS away from the administrative functions related to the collection and other licensed databases. One system cannot do all of this effectively while still clinging to the vestiges of a card catalog. Not all of this is the fault of the OPAC. Descriptive cataloging has not yet mastered bibliographic control of electronic or digital items with the same degree of expertise as it has the medium of print. Innovative OCLC-led projects such as InterCat and Cooperative Online Resource Catalog (CORA) experimented with the ability of OPACs and the MARC format to access and describe electronic objects. Much progress has been made, specifically in describing and providing access to e-journals, but, despite great strides forward, library systems still lag behind many of their Web search engine counterparts. More work is needed to create descriptive metadata that focuses on content, not containers, and public displays that distill for users the information they require to find and retrieve items while, at the same time, balancing the needs of libraries for full, robust, standardized record keeping. An OPAC can only display and interpret the information it contains. It cannot make up for inefficiencies in the catalog record.

CONCLUSION

It is becoming more and more clear that in the future library catalogs will no longer retain their exclusive role

as the sole portal to the collection. More and more items are being cataloged in separate registries or via links and portal systems. The catalog becomes, then, one of many access tools. What is not clear is what will be the connecting force between all of these registries and the catalog.

MARC was created as a method of communicating bibliographic information. It is not necessarily the best method for organizing information within a database. New, more object-oriented methods have developed since MARC came on the scene. Mark-up languages such as XML as well as developments in descriptive metadata will improve functionality of the OPAC and allow for a more flexible container or packet structure for the data. Leveraging these technologies would make OPAC function more flexible and allow for the integration of other data structures. All of these technologies also play into the OPACs function as a user interface for the catalog. Compared to other search engines prevalent on the Internet, the OPACs interface seems very dated.

Library automation vendors vie with each other to deliver a system that can stand as a true client/server, multitiered, graphical, Web-enabled, Unicode-enhanced, object-oriented integrated library system built on an industry-standard relational database management system.^[6] And so the standard is set for the current generation of library automation systems. The OPAC's general characteristics will include a client/server architecture; support for multiple character sets, preferably through Unicode; a windows-based graphical user interface for library staff; a Web interface for library users; use of a standard relational database system; a Z39.50-compliant server; import and export of MARC records; and Electronic Data Interchange (EDI).^[6]

Abstract

This entry introduces ontologies as a potential “silver bullet” for knowledge management, enterprise application integration, and e-commerce. Ontologies enable knowledge sharing and knowledge reuse. The degree to which an ontology is machine-understandable, its formality, is determined by the language used for the specification of the ontology. There exists a trade-off between the expressiveness of an ontology language and the modeling support it provides for the ontology developer. This entry also describes how different knowledge representation formalisms, together with the Web languages XML and RDF, have influenced the development of the Web ontology language OWL.

INTRODUCTION

The current Web and current enterprise application integration (EAI) systems lack standards and formal descriptions that impede information sharing and reuse, and cooperation between individuals and organizations. This problem is illustrated in the Web while performing a search. A search query typically returns many unrelated results, and information from such search results needs to be manually extracted from the source and manually combined with different sources. Inside organizations this problem is illustrated by the overlap in the data maintained by many applications. This overlap is often hard to detect. Even when such an overlap is identified, it is hard to deal with because the relation between data in different applications is often difficult to precisely characterize.

Ontologies can potentially solve these problems by facilitating knowledge sharing and reuse through formal and real-world semantics.^[1] Ontologies, through formal semantics, are machine understandable. A computer can process data annotated with references to ontologies and through the knowledge encapsulated in the ontology deduce facts from the original data. Ontologies make knowledge explicit, thus making it easier to see what kind of data are maintained by an application and to understand the meaning of the data. Therefore, ontologies facilitate the discovery of overlaps, and thus enable interoperability between heterogeneous systems. Furthermore, ontologies are intended to be shared models of a certain domain facilitating cooperation between different applications and even between different partners within that domain.

ONTOLOGIES AND THE SEMANTIC WEB

The term “ontology” originally comes from philosophy, where it stands for the universal theory of existence. The term ontology has been adopted by several Artificial Intelligence (AI) research communities; these were originally the knowledge engineering, natural-language processing, and knowledge representation communities. In the late 1990s, the notion of ontologies also became widespread in fields such as intelligent information integration, information retrieval on the Internet, and knowledge management.^[2]

In AI, the term ontology refers to a description of a part of the world in a program. Ontologies were developed to facilitate knowledge sharing and reuse. A common definition of the term ontology, used by many researchers in the field of ontologies, is given in Gruber:^[3] “An ontology is a formal explicit specification of a shared conceptualization.” A conceptualization is an abstract simplified view of the world that we wish to represent for some purpose. The ontology is a specification because it presents the conceptualization in a concrete form. It is explicit because all relevant concepts and constraints of the domain are explicitly defined. It is formal, which means that the ontology should be machine processable. It is shared—the ontology captures consensual knowledge.^[2]

According to Fensel,^[1] ontologies, through formal, real-world semantics, and consensual terminologies, interweave human and machine understanding. The real-world semantics are not captured by Gruber’s definition, but we feel that this is a very important property of ontologies. It is the real-world semantics that allow sharing and reuse of ontologies by both humans and machines.

A reason for the increasing interest in ontologies nowadays comes from the development of the Semantic Web.^[4] The Semantic Web can be understood as knowledge management on a global scale. Tim Berners-Lee, inventor of the current World Wide Web and director of the World Wide Web Consortium (W3C), envisions the Semantic Web as the next generation of the current web, where the information will be machine readable and the services will be automated. According to Fensel^[1] “The explicit representation of the semantics underlying data, programs, pages, and other web resources will enable a knowledge-based web that provides a qualitatively new level of service.” Ontologies provide such an explicit representation of semantics. The combination of ontologies with the web enables overcoming of many of the problems in knowledge sharing and reuse and information integration.

Ontologies interweave human and computer understanding of symbols. These symbols, also called terms (We mean here by “term” the word which is used to specify a certain concept.) and relations, can be interpreted by both humans and machines.

The meaning for the human is presented by the term itself, which is usually a word in natural language, and by relationships between terms that are understandable to humans. An example of such a human-understandable relationship is the superconcept–subconcept relationship (often denoted by the term *is-a*). This relationship denotes the fact that one concept (the superconcept) is more general than another (the subconcept). An example would be the superconcept person, which is more general than the subconcept student. Fig. 1 shows an example concept hierarchy (taxonomy), where the more general concepts are located above the more specialized concepts.

Concepts describe a set of objects in the real world. For example, the concept PhD-Student aims to capture all existing Ph.D. students. One such Ph.D student is Peter, modeled in Fig. 1 as a box. Peter has an instance-of relationship to the concept PhD-Student. This instance-of relationship means that the actual object is captured by the concept PhD-Student. Because of the formal relationships between the concepts PhD-Student, Student, Researcher, and Person, Peter must also be an instance of the concepts Student, Researcher, and Person.

These relationships are fairly easy to understand for the human reader. As the meaning of the relationships is formally defined a machine is able to reason with them and draw the same conclusions as the human reader. That which is implicitly known to humans (a human knows that every student is a person), is formally and explicitly encoded into these relationships, so that they can then be understood by a machine. In a sense, rather than the machine gaining real “understanding,” it is able to process “understandings of humans” and draw conclusions through logical reasoning.

Fig. 1 Example *is-a* hierarchy (taxonomy).

Types of Ontologies

There exist many different ontologies built for many different types of applications, which vary in the detail they express and the generality of their uses.

WordNet, for example, aims to cover all of the English language by providing a natural-language description for each English term and then specifying simple relationships, such as synonym (equivalent terms) and hyper-/hyponym (more/less general terms), between terms.^[5] The scope of WordNet is very broad (all of the English language), the level of detail is relatively low, and the relationships are quite simple. The term descriptions are limited to natural language and are thereby not machine understandable.

Cyc is another example of an ontology with a very broad scope attempting to capture all commonsense knowledge (e.g., space and time), but with a high level of detail.^[6] There are many very strict formal relationships between different terms. These formal relationships are machine-understandable.

We will refer to the scope of the ontology as the generality of the ontology; the level of detail is the expressiveness of the ontology. We provide a more detailed description of the generality and expressiveness of ontologies below and use these as dimensions to classify existing ontologies.

Generality of Ontologies

Because ontology is a specification of a shared conceptualization within a particular community, domain experts, users, and designers need to agree on the concepts and relations that are specified in the ontology. Such an agreement can be difficult to achieve. By layering the necessary knowledge in different ontologies based on generality, all parties need not agree to all ontologies. Agreement on the concepts and relations in the ontology is only required for

the utilized top-level ontologies and for the specific domain and application ontologies.^[7]

In the literature, we generally find three common layers of knowledge, corresponding to three different types of ontologies, based on their levels of generality, namely:^[1,2,8,9]

- *Generic (or top-level) ontologies*: Capture general, domain-independent knowledge (e.g., space, time, etc). Examples are WordNet and Cyc. Generic ontologies are shared by a large number of people across different domains.^[5,6]
- *Domain ontologies*: Capture the knowledge in a specific domain. An example is UNSPSC, which is a product classification scheme for vendors.^[10] Domain ontologies are shared by the stakeholder in a domain.
- *Application ontologies*: Capture the knowledge necessary for a specific application. An example could be an ontology representing the structure of a particular web site.

The separation between these three levels of generality is not always strict. For example, WordNet contains some domain-specific relations and Cyc contains domain-specific microtheories (modules of the ontology).

Although sometimes other types of ontologies (such as representational ontologies or task ontologies) are distinguished, the above three types of ontologies are commonly referred to in the literature and serve as the most useful separation of ontology types according to generality.

Expressiveness in Ontologies

Orthogonal to the generality of ontologies is their expressiveness. The expressiveness of ontology is typically, but not necessarily, determined by the ontology language; the expressiveness of the ontology language is the upper

bound for the expressiveness of the ontologies that are specified using this language. We distinguish several levels of expressiveness partly based on the ontology spectrum introduced in McGuinness^[11] (see also Fig. 2). These are:

Controlled vocabulary: A list of terms. An example is Dublin Core.^[12]

Thesaurus: Relations between terms, such as synonyms, are additionally provided. An example is WordNet.^[5]

Informal taxonomy: There is an explicit hierarchy (generalization and specialization are supported), but there is no strict inheritance; an instance of a subclass is not necessarily also an instance of the superclass. An example is the Yahoo! Dictionary.^[13]

Formal taxonomy: There is strict inheritance; each instance of a subclass is also an instance of a superclass. An example is UNSPSC.^[10]

Frames: A frame (or class) contains a number of properties and these properties are inherited by subclasses and instances. Ontologies expressed in resource description framework schema [RDF(S)] fall in this category.^[14]

Value restrictions: Values of properties are restricted (e.g., by a data type). Ontologies expressed in OWL Lite (see the section on “Ontology Language” below) fall in this category.

General logic constraints: Values may be constraint by logical or mathematical formulas using values from other properties. Ontologies expressed in OWL DL (see the section on “Ontology Language” below) fall in this category.

General logic constraints: Very expressive ontology languages, such as those seen in Ontolingua or CycL, allow first-order or even higher-order logic constraints between terms and more detailed relationships, such as disjoint classes, disjoint coverings, inverse relationships, part-whole relationships, etc.^[6,15] Note that some of these detailed relationships, such as disjointness of classes,

Fig. 2 An ontology expressiveness spectrum.

are also supported by OWL DL (and even OWL Lite), which indicates that the borders between the levels of expressiveness remain fuzzy.

Besides the distinction between different levels of expressiveness, Fig. 2 also shows the distinction between lightweight and heavyweight ontologies, as introduced in Corcho,^[16] as well as several examples of ontologies according to their location in the ontology expressiveness spectrum. Lightweight ontologies include concepts, properties that describe concepts, relationships between concepts, and concept taxonomies. Heavyweight ontologies also (perhaps instead of “also” you could write “extend lightweight ontologies to”) include axioms and constraints, such as value and cardinality restrictions.

ONTOLOGY LANGUAGES

In the areas of knowledge engineering and knowledge representation, interest in ontologies really started taking off in the 1980s with Knowledge Representation systems, such as KL-ONE and CLASSIC.^[17,18]

An important system for the development, management, and exchange of ontologies in the beginning of the 1990s was Ontolingua, which uses an internal KIF (Knowledge Interchange Format) representation, but is able to interoperate with many other Knowledge Representation (ontology) languages, such as KL-ONE, LOOM, and CLASSIC.^[15,19]

The languages used for ontologies were determined by the tool used to create the ontologies. Systems like KL-ONE, CLASSIC, and LOOM each used their own ontology language. The Ontolingua system was capable of translating ontologies between different languages using the KIF language as an interchange language. The languages and tools can be understood as interdependent, but also somewhat orthogonal, where we have the language on one axis and the tool on the other. For example, KL-ONE, CLASSIC, and LOOM all have their basis in Description Logics, while KIF has its basis in first-order logic.^[20]

In the early 1990s, KIF could be seen as a standard for ontology modeling. The language was used in prominent tools, such as Ontolingua, and in important ontology engineering projects, such as TOVE (Toronto Virtual Enterprise) and The Enterprise Ontology.^[21,22]

Later on in the 1990s, ontologies began to be applied to the World Wide Web. SHOE, for example, used ontologies to annotate web pages using formal ontologies embedded in HTML documents.^[9] Ontobroker and its successor On2broker, developed in the late 1990s, uses ontologies not only to annotate web pages, but also to formulate queries and derive answers.^[23] Ontobroker (and On2broker) provides an annotation language, which is used to annotate HTML documents with references to ontologies. The ontology (the terminology used by the annotation language) is specified using the representation

language based on F-Logic.^[24] Finally, Ontobroker uses a query language for the retrieval of documents based on their annotations. This query language is a subset of the representation language.

These ontology languages have all influenced the ontology languages for the Semantic Web. Below, we describe the different languages on the Semantic Web. We describe the history and development of the ontology languages in the context of the Semantic Web, starting with RDF(S) and moving to OWL.

Toward an Ontology Language for the Semantic Web

In this section, we describe the languages that are used to enable the Semantic Web and provide a basis for the development of ontology languages for the Semantic Web. The goal of such development is to establish one Web ontology language, developed by the W3C, as well as other web-enabled ontology languages, which will collectively form a basis for the W3C OWL language.

In the late 1990s the idea of a Semantic Web boosted the interest in the development of ontologies even further.^[4] The general conviction, held by the W3C, is that for the Semantic Web an ontology language needs to be developed that is both compatible with current Web standards and layered on top of them. The language needs to be expressed in XML and preferably layered on top of RDF(S) (see the subsections below for an overview of these languages). We will present the Web ontology language OWL, which has been developed as an ontology language for the Semantic Web.

An (perhaps too) often used depiction of the vision of Semantic Web languages, originally presented at XML2000 (<http://www.w3.org/2000/Talks/1206-xml2k-tbl/slide10-0.html>) by Tim Berners-Lee, is shown in Fig. 3. This so-called Semantic Web language Layer Cake depicts the different kinds of languages envisioned to be used on the Semantic Web. The layering of languages on the Semantic Web is both a syntactic and a semantic layering of languages.

The two bottom layers in the Layer Cake, Unicode-URI and XML (Schema), consist of existing standards and provide a syntactical basis for the Semantic Web languages. Unicode provides an elementary character-encoding scheme, which is used by XML. The Uniform Resource Identifier (URI) standard provides a means to uniquely identify and address documents and, more generally, resources, on, but also outside, the Web. All concepts used in the languages located higher in the Layer Cake can be specified using Unicode and are uniquely identified by URIs.

We will describe the XML, RDF(S), and ontology layers below. We will not cover the Logic, Proof, and Trust layers here. The Logic layer on top of the ontology language layer in the Semantic Web tower seems a little strange because current ontology languages have a good

Fig. 3 The Semantic Web Language Layer Cake.

Source: <http://www.w3.org/2000/Talks/1206-xml2k-tbl/slide10-0.html>.

grounding in logic. There is some debate on this logic language layer; some say a more expressive logic language should be layered on top of the ontology language.^[25] It could also be argued that this is not an appropriate layering; that the ontology language should be the top language and that applications should use it directly. However, there is a general conjecture that a more expressive rule language is required. There is currently a proposal for a Semantic Web Rule language, which is layered on top of OWL.^[26] The Proof and Trust layers are not well understood, but most likely refer to the application and not to some specific language (the application could prove some statement by using deductive reasoning and a statement could be trusted if it is proven and digitally signed by some trusted third party). The user would very likely play an important role in the Trust layer because it is the user that should decide whether or not some information source should be trusted.

Extensible Markup Language

Extensible Markup Language (XML) is a language for describing data in a structured or semistructured manner.^[27] Data are described using a number of tags with arbitrary names that can contain other tags or arbitrary data. A tag may contain attribute-value pairs. Furthermore, tags can be nested yielding a tree-based data structure. The names of the tags can be chosen arbitrarily by the creator of the XML document. This means that an XML document can be understood by a human reader if the name of the tags and the structure are chosen with care by the author and the reader understands the language used by the author. But even then problems can arise, because different people have different associations with terms. For example, some people would argue that the concept “Animal” includes humans, whereas others might

feel uncomfortable being classified as an animal, and thus do not consider the term to include humans.

Because an XML document is formally structured using tags, it is possible to process the document using a machine if there is an agreement about the structure of the document [using a document type definition (DTD) or XML Schema, discussed below]. However, a machine cannot understand the meaning of an XML document, as the tags are arbitrarily chosen by the author. The data in an XML document can only be processed in a prescribed way by organizing tags in a specific syntactical structure. The major benefit of using XML as the foundational layer of other languages is the fact that it presents a standardized way of representing data structures. Structures in higher-level languages can be mapped to structures in XML. Furthermore, XML makes use of the URI concept and provides namespace support. Also, XML enables the use of Unicode for character encoding and provides a standardized way of identifying the character encoding of a document.

An example XML document is shown in Fig. 4. The root element is “student,” denoted by the <student> start and the </student> end tags. All data are enclosed in elements nested within this root element.

If the XML document from Fig. 4 is sent from one machine to the other, the other machine can only process the document if it knows the schema of the document (i.e., the exact syntactical structure) and if it knows how to process the data enclosed in the document.

We illustrate this requirement of being aware of the exact schema and the way of processing each element with the XML document in Fig. 5. One can see that both XML documents aim at representing exactly the same information. The data in both documents have the same meaning (i.e., the same semantics), but the way it is represented (the syntax or structure) is different. For example, where the document in Fig. 5 uses the element PhD-Student to denote a Master’s student, the document in Fig. 4 uses the Student element, together with a Type element containing the data PhD, to denote a Ph.D. student. A human looking at the documents can see that they both represent the same student. A machine processing the document, however, does not see the similarity between the two documents because it has no means of relating different names and different structures.

```

```

Fig. 5 Sample XML document “PhD-Student.”

XML can be used as a format for data exchange between machines, in which case all parties taking part in the exchange need to agree on a common structure for the XML document, a common DTD or XML Schema. Furthermore, all parties need to agree on how to process these structures, i.e., they need to agree on the semantics of the XML tags, even though XML does not provide support for this. Another possible use of XML, as it is done in the Semantic Web, is to use it as the serialization language for other languages. This has the additional advantage of the possibility of reuse of many XML parsers, validators, and other XML-related tools.

Document type definitions

The structure of an XML document can be described using a DTD. A specific DTD describes the constraints on the structure of an XML document for it to be valid with respect to that DTD. A DTD describes the structure of a class of XML documents. Agreement on a DTD between different parties allows exchange of XML documents that conform to the DTD. However, note that only agreeing on a specific DTD is not enough for understanding all valid XML documents, as only the structure (the allowed tags) is described and not the meaning of these tags. A simple DTD describing the class of XML documents to which the document of Fig. 4 belongs is shown in Fig. 6.

XML Schema

Just like DTD, XML Schema is used as a language to describe classes of XML documents. As with DTD, the structure of XML documents is prescribed by the schema.^[28] A major difference between DTD and XML Schema is the fact that the latter has a broad range of (simple) data types (e.g., string and integer) and the

```

<!ELEMENT student (name, type, birthdate, email)>
<!ELEMENT name (#PCDATA)>
<!ELEMENT type (#PCDATA)>
<!ELEMENT birthdate (#PCDATA)>
<!ELEMENT email (#PCDATA)>

```

Fig. 6 Document type definition for “student” example.

possibility to form (arbitrarily) complex data types. An example of XML Schema for the class of XML documents to which the document in Fig. 4 belongs is shown in Fig. 7.

Because XML Schema also allows for the specification of many types of constraints, it would be a more suitable candidate for an ontology language than DTD. The main problem with an XML Schema is that it describes the physical structure (syntax) of an XML document but not the meaning (semantics) of the data. The relationship between ontology and XML Schema can be seen as analogous to the relationship between a conceptual database schema (e.g., an EER diagram) and a physical database schema (e.g., a relation database schema).^[29]

Klein et al. examined the relation between a specific ontology language, namely, OIL, which is a predecessor of OWL (see below), and XML Schema.^[29,30] One of the results of the comparison was that OIL has more expressive power when it comes to expressing knowledge and XML Schema has more expressive power when it comes to the structure of the data (e.g., there is no such thing as ordering in OIL) and data types (there are no data types other than string in OIL and to completely axiomatize different data types would be complex; OWL adopts XML Schema data types). Here again, it is stressed that ontology provides a domain theory and not the structure of a data container (like an XML Schema does), which explains most of the differences between the two.

Resource Description Framework Schema

The RDF is the first language developed especially for the Semantic Web. It was developed as a language for adding machine-readable metadata to the existing data on the web. It uses XML for its serialization to realize the layering as depicted in the Semantic Web Language Layer Cake (Fig. 3). Resource description framework schema extends RDF with some basic (frame based) ontological modeling primitives.^[14] There are such primitives as classes, properties, and instances. Also, the instance-of, subclass-of, and

```

<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema">
  <xs:element name="student">
    <xs:complexType>
      <xs:sequence>
        <xs:element name="name" type="xs:string"/>
        <xs:element name="type" type="xs:string"/>
        <xs:element name="birthdate" type="xs:date"/>
        <xs:element name="email" type="xs:string"/>
      </xs:sequence>
    </xs:complexType>
  </xs:element>
</xs:schema>

```

Fig. 7 XML Schema for “student” example.

Fig. 8 Sample RDF graph.

subproperty-of relationships have been introduced enabling creation of class and property hierarchies.

The RDF(S) (referring to the combination of RDF and RDF Schema) is not very expressive compared to many other ontology languages, as it just allows the representation of concepts, concept taxonomies, and binary relations. In the ontology expressiveness spectrum of Fig. 2, RDF(S) has the expressiveness of formal taxonomies combined with frame-based representation.

Resource description framework has the subject–predicate–object triple, commonly written as P(S,O), as the basic data model. An object of a triple can in turn function as the subject of another triple, yielding a directed labeled graph, where resources (subjects and objects) correspond to nodes and predicates correspond to edges. Furthermore, RDF allows a form of reification (a statement about a statement), which means that any RDF statement can be used as a subject in a triple; however, reification is not reflected in the formal semantics of RDF, and thus no additional conclusions can be drawn from the use of reification. A sample RDF graph is shown in Fig. 8. The corresponding triples notation is shown in Fig. 9; the RDF/XML serialization is shown in Fig. 10.

An XML Schema prescribes the order and combinations of the tags (the structure) in an XML document. In contrast, RDF Schema only provides information about the interpretation of the statements given in an RDF data model, but does not say anything about the syntactical appearance of the RDF description. Resource description frameworks can, in fact, be seen as an extension to RDF. Resource description frameworks provide for a means to define classes, class hierarchies, properties (binary relations), and property hierarchies. The classes and properties of RDF(S) can be instantiated in RDF (Fig. 11).

We have described the foundational Semantic Web languages XML and RDF(S). These languages are used as the lower layers in the Semantic Web Language Layer Cake, on top of which more expressive languages can be layered.

```

(hasName, #john1, #johnsmith)
(firstName, #johnsmith, "John")
(lastName, #johnsmith, "Smith")
  
```

Fig. 9 RDF triples.

OWL

Using the DAML+OIL language^[32] as the basis, the W3C Web Ontology working group has created a new ontology language for the Semantic Web; one that implements true layering on top of RDF(S) and incorporates the wishes of many stakeholders, both academic and industrial. The Web Ontology Language OWL consists of a set of three strictly layered dialects, namely OWL Lite, OWL DL, and OWL Full.^[33] This means that OWL Lite is a subset of OWL DL and OWL DL is a subset of OWL Full.

OWL is an extension of RDF(S). There are, however, some problems when layering OWL on top of RDF(S).

In Fig. 12 we see a very simple example of OWL, corresponding to the “student” example introduced earlier (see Fig. 4). Because of the very verbose RDF/XML syntax, this example is very hard to read. Fig. 13 presents the abstract syntax form of this simple OWL ontology. Note that the abstract syntax can only be used for the OWL Lite and OWL DL sublanguages. Note also that even the abstract syntax is quite complex for such a simple definition (just one class with four properties). This complexity originates from the Description Logic origins of OWL. The properties are defined separately from the classes instead of as a part of the classes.

It is possible to define the local property restrictions in OWL, thereby regaining some of the frame-based modeling possibilities originally introduced in OIL.^[32]

Fig. 11 Example of RDF(S) ontology.

Problems with OWL and Language Layering on the Semantic Web

In the language layering on the Semantic Web, we can distinguish syntactic layering (RDF uses a subset of XML, so every RDF document is valid XML) and semantic layering (every valid RDF statement must be a valid OWL Full statement). There is syntactic layering between Unicode, XML, and RDF and semantic layering between RDF and RDF schema [i.e., the RDF(S) meaning of constructs incorporates the RDF meaning of constructs] and now also between RDF(S) and OWL Full.^[25]

The following are the problems we have found with the current OWL language and the layering on top of RDF(S).^[1,25,34]

- It is not possible to fully layer a Description Logic-style language on top of RDF(S). The first problem is the fact that in RDF(S) keywords in the language are allowed to occur in RDFS ontologies. For example, one can create subclasses of `rdf: type`. Using the language constructs in the language itself is not possible in a first-order framework, because first-order logic does not allow for redefinition of the language. The second problem is the mixing of identifiers for classes, properties, and individuals. In RDF(S), the same individual can be a class and an individual at the same time. This cannot be captured in a first-order framework, because predicates are not allowed to occur in the place of terms.
- OWL Lite is the least expressive of the species of OWL. However, it still requires a fully fledged Description Logics reasoner and is therefore not as “Lite” as it seems. It turns out that features such as disjunction and negation can be expressed in OWL Lite, even though these constructs are not explicitly

```

<rdf:RDF>
  <owl:DatatypeProperty rdf:about="#birthdate">
    <rdfs:domain>
      <owl:Class rdf:about="#student"/>
    </rdfs:domain>
    <rdfs:range rdf:resource="&xsd:date"/>
  </owl:DatatypeProperty>
  <owl:DatatypeProperty rdf:about="#name">
    <rdfs:domain>
      <owl:Class rdf:about="#student"/>
    </rdfs:domain>
    <rdfs:range rdf:resource="&xsd:string"/>
  </owl:DatatypeProperty>
  <owl:DatatypeProperty rdf:about="#type">
    <rdfs:domain>
      <owl:Class rdf:about="#student"/>
    </rdfs:domain>
    <rdfs:range rdf:resource="&xsd:string"/>
  </owl:DatatypeProperty>
</rdf:RDF>

```

Fig. 12 Example of OWL ontology.

represented in the syntax. Horrocks^[35] shows how several features of OWL DL can be expressed using the constructs of OWL Lite. In fact, the only features in OWL DL that cannot be expressed in OWL Lite are

```

Class(a:student)

  DataProperty(a:birthdate
    domain(a:student)
    range(xsd:date))
  DataProperty(a:email
    domain(a:student)
    range(xsd:string))
  DataProperty(a:name
    domain(a:student)
    range(xsd:string))
  DataProperty(a:type
    domain(a:student)
    range(xsd:string))
)

```

Fig. 13 OWL example using abstract syntax.

arbitrary number restrictions and nominals (individuals in class descriptions).

- OWL DL is a language created by a standards committee, and is thus necessarily a compromise between the wishes of different stakeholders. The most important design goal was to create a sublanguage for which the satisfiability problem is decidable. OWL DL is equivalent to the SHOIN(D) Description Logic.^[36] It is known that this language is decidable, but there are currently no reasoners for this language, nor is there a known algorithm for deciding satisfiability of OWL DL ontologies. The major problem is dealing with nominals (individuals in class definitions). Arguably, it would have been better to restrict the language to SHIQ(D), which underlies the OIL language, a predecessor of OWL. Several optimized algorithms and implementations have been developed for reasoning with SHIQ, such as Racer and FaCT++.
- OWL Full is completely semantically layered on top of RDF(S). In this respect, it accommodates all wishes for a Web ontology language. However, the semantics for OWL Full are very hard to understand and entailment in OWL Full is not computationally decidable.^[37] Furthermore, ontologies provide a vocabulary for more expressive language in the Language Layer Cake (see Fig. 3), such as rule languages, and as a result this undecidability is propagated to the higher layers.
- Current proposals are for rule languages on top of the OWL layer on top of the OWL DL species, because of the nonstandard semantics of OWL Full and the nondecidability of the language. The most prominent proposal for a Semantic Web rule language is SWRL, which layers on top of OWL DL.^[26] Because SWRL combines the full expressive power of an expressive Description Logic with the full expressive power of (function free) Horn Logic, the language is in general undecidable.^[26]

We think OWL Full will probably not be used very much on the Semantic Web because the semantics is very hard to understand and it is very hard to deal with in an automated way. Even now, most research involving OWL focuses on OWL DL. Most practical applications will most likely use a subset of OWL DL, which is efficiently computable. However, wide-scale application of OWL on the Semantic Web will have to show what requirements arise when the language is actually put to use. It can, however, be argued that entailment (proving that one ontology is the logical consequence of the other; this is the problem that is undecidable in OWL Full) will not be the most common reasoning task, in which case OWL Full can be very useful.

For a more elaborate critique of the different species of OWL and language layering on the Semantic Web, we refer the reader to de Bruijn.^[38]

CONCLUSIONS

We have introduced ontologies as a potential “silver-bullet” (cf. Fensel^[1]) for knowledge management, EAI, and E-commerce (which is in fact EAI on an interorganizational level) for the following practical reasons:

- Ontologies are shared by a group of stakeholders in the domain.
- Ontologies interweave formal semantics with real-world meaning.
- Ontologies relate a human-understandable domain description with a machine-understandable description.

Because of these attractive properties, ontologies enable knowledge sharing and knowledge reuse. However, it turns out that we are not done with the introduction of the concept of ontologies. The degree to which an ontology is machine-understandable, its formality, is determined by the language used for the specification of the ontology. This also applies to the expressiveness of the ontologies (i.e., the degree of detail to which the domain can be described in the ontology), which is limited by the expressivity of the ontology language.

Actually, what an ontology looks like and what can be expressed by an ontology are entirely determined by the ontology language used. We have also seen that there exists a trade-off between the expressiveness of an ontology language and the modeling support it provides for the ontology developer. The use of Description Logics^[20] in current ontology languages, such as OWL,^[33] limits the understanding of developed ontologies, because of the decoupling of classes and properties. Fully fledged inferencing is necessary to determine the properties for certain classes.

We have described how different knowledge representation formalisms, such as first-order logic, frames, and Description Logics, together with the Web languages XML and RDF, have influenced the development of the current Web ontology language OWL.

The existence of version 1.0 of OWL does not mean the development of ontology languages will stop. Horrocks et al. identify several possible future extensions and improvements of OWL, which include support for modularization, closed world reasoning, and the unique names assumption.^[35] Furthermore, there is a current proposal for a Semantic Web rule language, which has been submitted to the W3C.^[26]

Open Access Scholarship and Publishing

Malcolm Getz

Department of Economics, Vanderbilt University, Nashville, Tennessee, U.S.A.

Abstract

Open access publishing helps scholars to be more productive and to reach larger audiences. The challenge for entrepreneurs and universities is to design systems for publishing that take advantage of the digital technologies, offer substantial intellectual value, and are cost effective. Authors, publishers, libraries, and readers are changing their roles as the methods of financing publication shifts in part from readers to authors.

INTRODUCTION

At the beginning of the twenty-first century, the growth of the Internet changed the economics of scholarly publishing. The dramatic and sustained increases in prices of paper-based materials had narrowed access to scholarship.^[1] In contrast, the publication of digital materials on the Internet expanded and accelerated access and lowered costs. Indeed, substantial quantities of high-quality material became available to readers worldwide without charge. Such open access scholarship changed the relationship between authors and readers with fundamental shifts in the roles of publishers and libraries. Open access publication supports collaboration, a wider range of publishing opportunities, and access to wider audiences. There is a concern, however, that its openness may foster disorder that may make it less valuable than it could be.

FROM CONVENTIONAL TO DIGITAL PUBLISHING

The conventional print books and periodicals of the twentieth century involved both the up-front cost of editing and typesetting along with the substantial variable cost of paper, printing, and mail for each copy shipped. Publishers earned revenue from selling subscriptions to their readers and libraries sufficient to cover both the up-front and variable costs. The publishers typically charged higher rates to libraries than to individuals, particularly for journals. For many scholarly books and journals, revenues to publishers from libraries were predominant, effectively paying for most of the publisher's up-front costs and more. For many journals, prices to libraries grew beyond plausible association with production and distribution costs.^[2] Moreover, the libraries incurred significant additional costs in managing their purchases, registering each item in a database to sustain control and

access, and providing space to store the materials.^[3] Under such pressure, library budgets did not expand enough to sustain their collecting programs. The number of publications and growth in the number of pages expanded faster than the purchasing power of library collection budgets and the libraries bought a smaller share of all that was available. In addition, print had considerable delays from the time an author submitted her work until it was in the hands of readers.^[4]

The digital revolution changed many of these costs while accelerating the process. Digital materials are often stored once on the Internet, or a few times for security, rather than on each campus. Materials offered by subscription may be licensed as whole databases rather than by individual title, reducing each library's processing costs. Open access materials particularly, but often all digital materials, are fully searchable by individual words with freely available search services that not only point to items by content but reveal the importance of the item in wider streams of scholarly work. The digital documents whether through open access or by database subscriptions are delivered directly to reader's workstations within a few seconds. Many digital publications put works in the hands of readers within a few months, sometimes within weeks. As the quantity of material available digitally exceeded the content of most conventional academic libraries, as the power of digital searching exceeded conventional indexing, and as a host of quality materials became instantaneously available at any workstation, the digital document took center stage from the published paper document as the standard medium of scholarly communication.

In 2007, *Ulrich's Periodicals Directory* listed more than 23,550 active, peer-reviewed, academic periodicals worldwide; 15,205 of them were available online.^[5] In August 2007 Ulrich's listed 1673 current, refereed academic journals as open access, 7% of the total. *The Directory of Open Access Journals* listed 2821 open, quality controlled academic journals, including many titles not

captured by Ulrich's.^[6] Of course, journals differ in intellectual reputation. One hallmark of quality is evaluation by ISI's *Journal Citation Reports* (JCR), as discussed more fully below. Ulrich's listed 6875 current, refereed, academic journals as being evaluated by the JCR, 29% of the total. Of the journals evaluated by JCR, 94% are available digitally and 4% (265 titles) are available in the open, a significant start.

FROM DIGITAL TO OPEN PUBLISHING

Whether a digital document will be supported by subscription or made available by open access depends on the extent of its up-front costs, the acceptance of fees paid by authors and funds from third parties, and the possibility of Internet advertising. Indeed, publishing strategies range from an author posting her work as-is on a personal Web site, freely available to all without review, editing, or promotion, to formal periodicals with creative editors who winnow large numbers of submissions, commission works by leading authors, rewrite author's drafts to improve style, include extensive graphics to enhance readability, and develop reputations for sustained intellectual influence. Up-front editorial costs will range, then, from zero to many thousands of dollars per essay. Open access, that is publication without charge to readers and libraries, dominates when editing costs are low. In contrast, significant revenue streams must support the intensity of editorial effort seen, for example, in *The New England Journal of Medicine* (Nature uses only a full-time editorial staff, located in nine offices around the world, <http://www.nature.com/nature/about/contact/editorial.html>. The editorial staff at NEJM appears at <http://content.nejm.org/misc/edboard.shtml>). A central issue in the development of open access publications is how much editorial service can be sustained with revenue streams from sources other than subscriptions?

A second issue for open access is the role of copyright. Lawrence Lessig, professor at Stanford Law School, launched the Creative Commons in 2001 to reduce the restrictions imposed by copyrights.^[7] Authors can retain the copyright to their own materials and grant limited rights of use to others instead of assigning all rights to a publisher. Many open access publications only require a nonexclusive right to publish materials. Authors may allow reuse, for example, by others for noncommercial purposes. The ready opportunity to reuse materials may promote more rapid intellectual advance much as Open Software makes significant progress by expansive collaboration.

E-PRINT SERVICES

Understanding the financial underpinning of open archives provides a basis for understanding the possibilities for open journals discussed below. Paul Ginsparg developed a

database of e-prints, that is, works-in-progress as well as published works, in high-energy physics beginning in 1991 at Los Alamos Labs that has become the dominant vehicle for physicists to share their work worldwide.^[8] ArXiv, now owned by the Cornell University Library, expanded to encompass most topics in physics, mathematics, quantitative biology, and statistics. The database includes about 500,000 essays, received nearly 5,000 new submissions in some months in 2007, and has upward of 500,000 connections per day (a measure of usage) at peak periods at the Cornell site with additional usage at several mirror sites around the world. Research Papers in Economics (RePEc) is a similar service that depends entirely on volunteer effort in 57 countries (The RePEc: Research Papers in Economics, repec.org) holds 470,000 items with 12,700 users and 10,250 participating institutions in 2007).

ArXiv provides a minimal screen of its submission, far short of editing. Authors register with the site and submit their work in a prescribed format. They may subsequently publish posted work in edited journals and works published in edited journals may be posted when consistent with the journal's copyright policies. Most of the processing of work into arXiv is automated. Readers search the database and download materials without charge. Cornell with some grant funds sustains the cost of the hardware, software, and modest staff for the arXiv service at a cost of under \$300,000 per year.

ArXiv, then, is an open access self-publishing service (i.e., the author posts the work in the open for anyone on the Internet to read). It is widely used and operates at modest cost per unit of service. Scholars in the relevant disciplines use arXiv to search for the latest work in their area. The processing provided by arXiv, primarily a cursory decentralized review, is designed to assure that submitted essays are within the subject scope of the service. The author's work appears as the author submits it, however authors may replace or withdraw their essays.

A similar service in economics and related fields is self-financed. Michael Jenson, an economist at the Harvard Business School founded the Social Science Research Network (SSRN) in 1994.^[9] It is privately organized and self-financed through sale of abstracting journals and other ancillaries, however, access to all author-uploaded papers in the SSRN database is free. Its annual budget is in excess of \$800,000, supporting a database of 50,000 essays with over 300,000 downloads per month.

SELF-ARCHIVING

The success of arXiv, SSRN, and similar open e-print publishing services along with the growth of the Internet led scholars in other disciplines to consider services that allow authors to post their drafts in the open and that also invite authors to post the articles they have published in

edited journals in the open. The up-front costs across all disciplines might be shared among many universities. One method of sharing the mostly fixed cost of universal, open access e-print services is to have each campus archive the work of its scholars in formats that could be readily indexed across all campuses and disciplines. To this end, the Open Society Institute launched the Budapest Open Access Initiative in 2001.^[10,11] Stevan Harnad, a research professor of Cognitive Science at Université du Québec à Montréal, is one of the leaders of the open access movement.^[12,13] Posting published, peer-reviewed work in open archives other than through a published journal is called green open access.^[14]

The Open Archive Initiative (OAI) propounded standards for metatags, that is, a method for labeling the author's name, the essay's title, subject, and date.^[15] When materials that are tagged in compliance with the OAI standard are posted to a compliant digital archive, the tagged information can be harvested by indexing software that spans all of the participating archives. Documents with tagged fields support more precise searching. A reader can then search the universe of open archives of all of the participating institutions, also called institutional repositories, as though they were all under one roof and identify and retrieve a document wherever it is stored. In 2007, there were 687 registered archives in 60 countries participating in the OAI with a total of over 6 million documents.^[16] DSpace, developed by MIT and Hewlett-Packard and released in 2002, is open source, OAI compliant software for managing digital archives.^[17] Institutional repositories are typically not specific to discipline and do not generate the attention of the discipline specific arXiv and SSRN.

Self-archiving under the OAI makes significant quantities of published material available to readers without charge. Libraries encourage open archiving as an antidote to expensive journal subscriptions.^[18] If all published material were available in this format, how would publishers generate revenue streams to support the editorial processes for their journals? The European Commission, the U.S. Congress, and the national legislatures of several other countries are considering laws to require that research that is funded by their governments be made available in open archives shortly after publication.^[19] Such legislation is typically supported by libraries but opposed by many scholarly publishers. Former Congresswoman Patricia Scott Schroeder, President and Chief Executive Officer of the Association of American Publishers, leads publishers on the issue.

WIKIPEDIA

Open publications using many volunteers with modest philanthropic support can create substantial digital publications. Wikipedia, a collaborative online encyclopedia

published in the open, gives a sense of the power and limits of open publication. Founded in 2001 by Jimmy Wales and Larry Singer, Wikipedia supported close to 2 million articles in the United States in 2007 with an annual budget of just over \$1 million in philanthropic funds.^[20] Requests for Wikipedia pages approach 30,000 pages per second at peak times. Although Wikipedia articles appear without authors' names, submissions go through a review process and conform to style guidelines that require entries be neutral in tone and based on peer-reviewed publications. Occasionally, articles appear that are biased, erroneous, or fraudulent (Virgil Griffith, a graduate student at CalTech, developed Wikipedia Scanner to identify the IP addresses of people editing Wikipedia entries. He found, for example, that negative information about WalMart and Diebold had been deleted by people located at these companies).^[21,22] The "discussion" section on each article provides reader comments. Problems flagged by readers may be changed in time through new submissions.^[23] In a sense, however, Wikipedia is permanently a work in progress. Some professors ban the citation of Wikipedia articles by their students, citing errors and biases, the lack of author attribution, and to give preference to primary sources.^[24] Wikipedia continues to evolve. In 2005 it began requiring contributors to register and it has introduced a more thorough review for "featured articles." Wikipedia also continues to invest in developing improved search software.

Wikipedia is the dominant encyclopedia on the Internet. Even though entries are often anonymous, scholars contribute and edit Wikipedia articles. Proponents of open access scholarly publishing, and indeed more generally of collaborative, network-based ways of doing intellectual work, have in mind technological and financial relationships that are similar to Wikipedia.^[25] Voluntary editorial effort, supported by modest levels of philanthropic or institutional funds, can sustain large-scale publications, freely available to all. The building blocks of such an environment in academia are open journals that require a formal review mechanism and post only attributed works.

OPEN JOURNALS

Open archives and Wikipedia provide limited mechanisms for supporting an editorial process. Careful review that assures relevance, quality, originality, and acknowledgment of related work is a hallmark of academic publication. If scholarship consisted only of archives of material that wasn't reliably reviewed, readers would be challenged to sort through large quantities of poorly differentiated materials in order to identify the most important ideas and to evaluate the quality of the content. Often even very creative scholars present their work poorly and important new ideas may be ignored until ratified by a distinguished editor. Effective editors provide the

valuable service of identifying the most important ideas, verifying accuracy, and polishing presentations to make them accessible to the intended audience.

Academic publication typically means that an editor has evaluated an author's work, often with the counsel of other scholars knowledgeable in the specific subject matter of the work. Such peer review helps keep new work focused on a specific audience, makes it more likely that the work both relates well to established ideas and adds something new, and that the style of presentation conforms to academic norms. Quality assurance allows an academic to concentrate on reading works that are sophisticated, original, relevant, and well written. In fact, editors of many higher quality journals select for publication from among many well-crafted and original submissions. In 2006, the 64 academic journals in biology that were evaluated by the ISI JCR published 5783 articles.^[26] A working biologist will choose carefully what to read among the torrent of new materials.

Fortunately, there are several ways beyond subscriptions to finance the editorial process that turns the authors' raw materials into journals of sufficient quality to be attractive to readers. One method involves institutional support for the hardware, software, and managing editor supplemented by a significant amount of volunteer effort by reviewers, that is, an arrangement much like Wikipedia. Historically, universities supported their presses to produce books and journals that help advance their campuses' intellectual reputations. Supporting an open journal can be less expensive.

Readily available software lowers the cost of managing the editorial process. The Public Knowledge Project, launched in 1998 at the University of British Columbia by John Wilinsky, Pacific Press Professor of Literacy Technology, created the Open Journal Systems software and makes it available for use on any campus without charge. It and similar software support a database environment that manages the flow of submissions to a journal, the process of review and editing, and the presentation of the digital journal online with full-text searching.^[27] With such software installed locally, a university can support scholars in launching and sustaining a digital journal at modest cost. As of 2007, the Open Journal Systems software supported the back-office functions of more than 900 journals worldwide, some supported by subscriptions and some in the open (A list of the journals is at <http://pkp.sfu.ca/ojs-journals>. Cornell University has developed alternative software. E-Journal, <http://drupal.org/project/ejournal>).

Theoretical Economics is an example of an open journal, launched in 2006 and managed with public domain software at the University of Toronto with a distinguished international editorial board.^[28,29] Authors pay a \$75 submission fee but may avoid a per page publication charge by putting their essays in a specific format for publication. The editors reach a decision on 90% of submissions within

90 days, a relatively short time for an academic peer-review process. The journal is available without charge via the Internet and sells its annual volume in print. Publishing in formally reviewed open journals is called gold open access publishing.

AUTHOR-FUNDED JOURNALS

A second strategy for open publication relies on publication charges to authors to finance the up-front and distribution costs. With the cost of distribution to another reader near zero, a zero price provides access to everyone on the Internet. If usage grows dramatically with the drop in price to the reader to zero, then the author-pays strategy may yield more generally useful publications than the reader-pays system. The likelihood of greater exposure for an author may make author-based finance more desirable than a reader-based financial strategy.

The shift from reader-pays to an author-pays regime is somewhat like the change in the charge for postage made in the 1850s. In the old policy, the recipient paid the postage in order to receive the mail, much as in a reader-pays regime for publications. After the 1850s, the U.S. Post Office introduced postage stamps and imposed the charge for delivery of mail on the sender.^[30] The post office has much lower costs in selling stamps than in collecting from each recipient for each separate piece of mail. The post office avoided the expense of attempting delivery of mail only to have it rejected. The shift to a sender-pays system allowed advertisers to use the mails to push unsolicited materials to customers, a change not necessarily welcomed by all recipients.

The *Public Library of Science* (PLOS) offers high-quality author-paid journals. It produces open journals with a high level of editing. PLoS launched its journal-publishing venture in 2003, a venture led by Harold Varmus, Nobel Laureate in Medicine, former head of the National Institutes of Health, and President of the Memorial Sloan-Kettering Cancer Center. BioMed Central, a comparable venture, began publishing open journals in the United Kingdom in 1999.^[31] Because the content of these journals is in the open, their articles are archived as part of the OAI and readily available to many Internet search engines. In 2007, the author fees were \$2750 for the top journals at PLoS (\$2410 at BioMed Central) per published article. Because dissemination of research results is an important part of grant supported research, the funding agencies often allow payment of author fees from grant funds. Because publications advance a scholar's reputation, salaries often increase with more publication. It is then in an author's interest to support payment when an article is published in a more widely cited journal. Universities gain intellectual reputation as their faculty publish, and it is then in the interest of universities to support author fees.

A university provost might compare the university's cost of a subscription journal plus the cost of tracking and processing the subscription through the library to the likely outlay of author publication fees of the university's faculty. If the expenditure on editing is the same per article, on average the net gain with the open journal with author fees arises from the smaller number of transactions with authors rather than with readers and the expanded readership with a zero price to readers. A university with a large number of faculty who publish in the journal might incur more cost with author fees, net of grant support for the author fees, than with subscriptions, net of the partial indirect cost recovery from grants based on library expenditures. Prestigious universities with highly productive faculty may, however, place a premium on the greater exposure their authors receive in open journals.

INFLUENCE OF OPEN JOURNALS

On their face, open journals look a little like vanity publishing, much as a hobbyist might publish a memoir for his family at his own expense. Many readers are less likely to read self-published works than those that have been reviewed and edited. On the other hand, open journals can be scrupulously edited and have more value by being more accessible.

One way of gauging the intellectual impact of a publication, that is, its value to readers, is to observe the frequency with which other writers cite it. A commonly used measure of a journal's intellectual value is the ISI Impact Factor as posted in the JCR.^[32] The Impact Factor is the ratio of the number of times the articles are cited in academic journals in the first 2 years after publication as the numerator to the number of articles published in a journal in a given year as the denominator. The median Impact Factor for 103 journals in medicine evaluated by ISI was 1.21 in 2006. Twenty-eight of BioMed Central journals were evaluated by ISI (among 100 it publishes) with a median Impact Factor of 2.74. BioMed Central's journals have impact. PLoS has five journals scored of seven it offers in medicine and biology with a median Impact of 7.67, far above the norm. PLoS Biology at 14.01 has the highest impact of 64 rated journals in biology and PLoS Medicine at 13.75 is the fifth highest among 103 rated journals in medicine. PLoS had the advantage of significant philanthropic support for its launch that enabled it to achieve extraordinary impact quickly and to build a reputation that should allow it to be self-sustaining with author fees. The high level of impact of PLoS and BioMed Central's journals clearly establishes that open journals can achieve high levels of intellectual quality. Articles in open journals are more likely to be cited and thereby enhance their authors' reputations more than subscription journals, other things equal.

Some publishers offer hybrid journals, with articles in the open with a substantial author publication fee combined with other articles available only by subscription without an author fee. For example, Springer, a publisher of over 1900 academic journals, offers Open Choice, its program that charges a \$3000 publication fee from authors to allow their article to be published in the open. Springer promises to adjust journal prices in light of the number of open choice articles published in the preceding year.^[33] Springer's journal, *Economic Theory*, for example, had a library price of \$1398 per year in 2007. It published about 120 articles per year with an Impact Factor of 0.50, compared to a median of 0.66 among 175 rated journals in economics.^[32] Two of the most recent 17 issues are available in the open, but no other individual articles are in the open in the 2006 volume.^[34]

A publisher is likely to prefer selling subscriptions to libraries instead of selling publication to authors. Journal quality, after all, depends on the quality of its authors and author fees could discourage them. Libraries show limited response to price increases; they tend to sustain their subscriptions. In contrast, authors are more likely to be influenced by author publication fees in selecting a journal. When demand is more responsive to price, suppliers find that setting price closer to marginal cost maximizes profit. A journal based on author fees is then likely to be less profitable than one based on subscription fees to libraries, other things equal. Self-financing publishers, whether for-profit or not-for-profit, may be more reluctant to move to author fees. They may then set author fees in hybrid journals well above the fees that might prevail when fully open journals are ready alternatives in a discipline. From the point of view of readers, a likely advantage of the growth of open publications is a reduction in the price of subscriptions for other journals. Authors must be persuaded of the higher probability of citation in open journals.

Another way to compare the intellectual impact of subscription with open journals is to consider the number of citations to articles published in the open to other articles in the same journal that are not in the open, while controlling statistically for the number of authors and the author's prior publication record and other attributes. One study compares citations to 212 openly published articles in the *PNAS: Proceedings of the National Academy of Sciences* to 1280 articles in same journal that are only available by subscription.^[35] Articles published in the open had more than twice as many citations 4–10 months after publication and nearly three times as many 10–16 months after publication, other things equal. Open publication is more valuable, given the reputation of the journal.

SUBSCRIPTIONS

Subscriptions continue to provide the dominant revenue stream for the support of the publication of academic

journals. The *American Economic Review* (AER), for example, goes to members of the American Economic Association. For \$90, the 18,000 members each get three journals and about 4000 libraries subscribe to the three-journal bundle at \$345 per year in 2007. The Association devotes about \$1.5 million to producing the AER with about 185 articles per year including those in a proceedings issue, that's about \$8000 per article.^[36] This figure is about three times that of the PLoS author fee. The *New England Journal of Medicine* has 200,000 subscriptions at \$149 for print and online, \$99 for online only, \$599 for libraries. It is generating about \$50 million per year in revenue associated with the *Journal*, offering 300 or so articles per year in its weekly publication (Massachusetts Medical Society: Waltham, MA, "2005990-RET Returns" reports \$106 million of total revenue for the year with expenditure of \$63 million on publishing. It lists eight publications on its website, <http://www.massmed.org>, of which the *New England Journal of Medicine* is the most important. Although the society does not provide detailed information about its expenditures, it seems reasonable to assume that \$50 million is spent publishing the journal). It is probably spending more than \$150,000 per article, although how much of the revenue is spent specifically on the publication is unclear.^[37] Although distribution costs for a weekly are significant, the cost of selecting about 300 articles from among 5000 submissions per year, two-thirds of which are from abroad, and editing those selected into more readable essays is substantial. Publishers, particularly of journals with a high level of editorial effort and a high volume of circulation, are likely to continue to depend on subscription revenue. Readers value quality editing and are willing to pay for it. Editors are readers' agents just as they are also author's agents.

High circulation publications can sustain relatively low-cost subscription rates because they spread their front-end costs among many readers. The gain to readers from offering the same content with a zero subscription fee may be less than for a publication with a high subscription rate. Subscriptions to some high circulation scholarly publications are likely to continue even as more open publications appear that are financed with author fees, philanthropy, and advertising. The boundary for scholarly publications is likely to continue to shift as technologies and reader tastes change just as the boundary may shift for popular newspapers and magazines. Some publications like the *New York Times* offered some digital content free with premium digital content available by subscription. In 2007, the *Times* shifted to an all-open format, viewing the gain in advertising revenue from general Internet access as more than sufficient to offset the loss in subscription revenue.^[38] Typically academic publications eschew advertising to focus reader attention on scholarship.

The timing of availability is an important dimension for academic publishing. Newspapers and magazines

obsolesce quickly. Academic journals have enduring value. ISI publishes a cited half-life for journals, an estimate of the number of years in which half of all citations that will ever occur have occurred. The median half-life for articles in 103 medical journals is more than 6 years; for history, it is over 10 years.^[32] A subscription publisher may then choose to offer online access to its content with a delay. The publisher imposes an embargo on online access to the full text of its content by online services in order to avoid cannibalizing subscription revenue. In effect, subscription buys immediate access while less restrictive or open access to full text online comes with a delay. Embargoes of 12 months are common for access to journals, as discussed below.

SEARCH AND INDEXES

In addition to attracting strong authors and providing effective editing, the intellectual success of publications depends on appearing in indexes and finding aids. Although readers find items by browsing, many also look for materials on specific topics when an interest arises. Finding aids migrated from print to digital ahead of the publications themselves because digital searching is more convenient than searching a printed index.

Printed indexes typically covered journals and books within a discipline. Professional indexers scanned each item as it was published, noted author and title and assigned a subject category. The index then showed citations to articles listed under subject categories with an index to authors, aggregated by year or less frequently.

The leading professional society in each discipline typically published an index for its discipline. For example, *Chemical Abstracts* began publication in 1907 and became part of the American Chemical Society in 1956. It first offered an online service in 1980. Its database contained more than 27 million bibliographic records in 2007.^[39]

A milestone in the launch of a new journal is when the appropriate indexing service includes the content of the new journal. For example, *Theoretical Economics*, an open journal launched in 2006, was indexed in *EconLit* from its first issue while the *International Journal of Economic Theory*, a subscription journal addressing a similar audience, was not indexed in *EconLit* even in its second year of publication.

With the digital revolution, the conventional indexes moved to digital media with search engines to provide faster, more comprehensive searching than can be achieved with print. Digital searching can identify materials by words in titles and abstracts and allow Boolean operators to control searches. With the success of the digital tools, the print version of indexes began to shrink and disappear. For example, the American Economic Association stopped publishing its *Index to Economic Articles* in 1996.

Other indexes have broader scope. The Institute for Scientific Information, for example, published the *Science Citation Index* beginning in 1961 to report the citations to prior works and now covers the content of more than 6400 journals in science and technology. Tracking references to other published literature allows building a bibliography that traces how ideas develop. It also provides a way to identify the importance of particular publications. The ISI Impact Factor, mentioned above, is a by-product of the *Citation Index*. The *Social Sciences Citation Index* indexes 1700 journals in the social sciences and the *Arts and Humanities Citation Index* tracks the contents of over 1000 journals.

The digital revolution made radical changes in indexing, epitomized by the founding of Google by Larry Page and Sergey Brin in 1998 while they were graduate students at Stanford University. Google, the largest search service on the Web, provides nearly 100 million searches daily.^[40] It gained dominance because of the quality of its method for ranking Web pages in response to a search. By counting and evaluating the linkages from other pages to a given page, a process called dynamic indexing, Google identifies pages that are more likely to be sought and presents them first. Dynamic indexing is superior to static indexing, that is, searching based only on the words in the article, even when the word search encompasses the full text of a document. Google generates substantial revenue from the advertising it sells that appears as part of typical result-screens on basic Web searches.

In 2004, Google launched *Scholar*, its free service for searching a large part of the scholarly literature in a single database. *Scholar* encompasses many journals, books, working papers, and government reports. It applies Google's powerful dynamic indexing search engine to retrieve results. It reports a count of materials that cite the item at hand and will provide a list of them. When copy-right allows, *Scholar* provides a link to the full-page images of the item, sometimes by linking through a local library's digital subscription. *Scholar* plays a key role in open access publishing by providing an open access index.

Critics of *Scholar* lament that *Scholar* uses a machine-created database that does not use systematic tagging of authors, titles, dates, and subjects.^[41] (The American Economic Association attempted to replicate assignment of its subject codes to articles using software and achieved only a 50% success rate. Private communication from the Secretary of the Association.) As a consequence, the result of a *Scholar* search often includes more extraneous items than a search of a carefully structured data file. Critics also note that Google does not describe what materials are included in the *Scholar* database. Users cannot be sure what literature they have missed with a *Scholar* search. Because databases differ, a *Scholar* search typically complements other searches. Because *Scholar* is free and simple, it is often the starting point for searches. Another generation of open indexes may invite readers to set tags to indicate their assessment of quality that then influence the importance of an item in a search result.^[42]

DATABASE INTEGRATORS

Another player in scholarly publishing is the database integrator, a firm that provides access to multiple databases with a common interface. A firm with suitable search software may license the use of databases from their publishers, for example the index databases of a number of scholarly societies, and, in turn, license an aggregation of the databases to libraries, using the integrator's common search software. Since the 1990s, a number of integrators began offering linkages to full text.

Ingenta, founded in 1998, launched a service called IngentaConnect in 2004 that provides access to the content of more than 31,000 publications with the full text of 8000 of them via the Internet, either by subscription through libraries or by direct pay-per-use. Ingenta reached agreement in 2004 to allow Google to index Ingenta's digital collection. Users can search Scholar for free and retrieve full text from Ingenta for a fee. In 2007, IngentaConnect processed 31 million sessions per month.

Also in 2004, Elsevier, publisher of 1900 academic journals, launched its latest search service, SCOPUS, as a digital service offered by subscription through libraries.^[43] In 2007, SCOPUS indexed 15,000 academic journals with abstracts, including 1000 open journals, 30 million abstracts, and 21 million patents with links to the content of many journals in full text. It also alerts readers to new items appearing in the database that match the reader's standing search query. Elsevier developed a Web search engine, Scirus, to identify and index only science-oriented pages on the Web. Access to a Scirus search is open.^[44] The SCOPUS subscription service includes the Scirus index of 275 million scientific Web pages.

Another major integrator is EBSCO. EBSCO markets its integration service to libraries, offering specific services by individual discipline. In 2007, its service for economics uses the American Economics Association *EconLit* index database to 1233 publications and provides links to the full text of 400 of them.^[45] Of these, 11 had embargoes of 6 months and 227 had embargoes of 12 months.

The National Library of Medicine (NLM) plays a number of roles, including being an integrator of a number of databases relevant to medicine and medical research. It began publishing *Index Medicus*, an index to the medical literature in 1876.^[46] It began creating a digital search and retrieval system in 1964 and put it online 1976. It made the MEDLINE service available in the open on the Internet in 1997. In 1996, it began offering links from the citations in MEDLINE to the full text of articles in PubMedCentral. These articles are then available in the open. MEDLINE abstracted about 5000 current journals in 2007 and contains more than 17 million citations. PubMed supports 3 million searches per day.^[47] The NLM has given significant support to the growth of open scholarly publication.

Academic libraries themselves also act as database integrators. They provide links from varied search services that allow a campus searcher to click to the library's full-text service for the item. Open access services both compete with and complement subscription services (For example, the Exlibris Group, <http://www.exlibrisgroup.com/index.htm>, offers to libraries software that integrates searches across disparate sources).

ADVERTISING

Although academic journals generally include few ads, database integrators have an opportunity to offer access to full-text academic journals in the open supported by advertising. In 2007, Elsevier launched OncologySTAT.com, an Internet portal with immediate open access to the current content of 100 of its own medical journals.^[48] Elsevier expects to earn more from advertising than it loses in dropped subscriptions. OncologySTAT.com will include synopses of articles published outside Elsevier and will include the full text of such articles once their embargoes expire. Elsevier's initiative suggests that advertising may support significant quantities of open scholarly publications in some disciplines. Elsevier's move to open publication supported by advertising is a part of a widespread movement including the *New York Times* and other mass publications.^[49]

BOOKS

Scholarly monographs have played a principal role in some disciplines, for example, history and the humanities, but the digital revolution is reshaping the place of books. The digital revolution for books began in 1971 in the early days of computing when Michael Hart invented e-Books and launched Project Gutenberg at the University of Illinois with the goal of making the full text of books freely available in digital format.^[50] Gutenberg had mounted 20,000 items in 2007. The World Public Library, founded in 1996, offered 75,000 titles without charge in 2007 and more than 500,000 total for a modest annual membership fee.^[51] The titles are generally old titles in the public domain rather than current publications. Producing digital books and making them available on the Internet either in the open or by subscription is technically no more difficult than offering digital journal articles. However, few people choose to read whole books online. Although several firms have marketed appliances for reading digital books that are nearly as portable as a conventional book, none to date have enjoyed wide appeal. For example, the Sony Reader System launched in January 2006.^[52] Sony offers several thousand titles for its reader through <http://ebooks.connect.com/>. Making digital books in page turners, *Business Week*, September 3, 2007.^[53]

Digital books appear to be successful in two other ways. First, digital access to the full text of a book allows the work to be readily searched, making the content

discoverable by general Web searches. Led by its Director, Scott Lubeck, the National Academy of Sciences Press offered access to all its books in the open online in 1994 and sales of print increases.^[54] In this case, the digital book was a complement to print.^[55] In 2004, Google reached agreement with several large academic libraries to digitize large blocks of each library's holdings.^[56] Materials out of copyright are made fully available in the open. For materials under copyright, Google's Book Search points to the work with links to libraries. Book Search is a very large and powerful book catalog available in the open.^[57] The site includes both links to publishers and booksellers as well as advertising.

Second, digital books offer ways of presenting color, graphics, and even extend to animation, video, and sound. Rice University announced the reopening of its press in 2007 as a publisher of digital materials exclusively, particularly books.^[58] Among other things, it intends to offer medical diagnostic books with rich color photographs and illustrations. Readers may read the works online in the open or buy print-on-demand copies.^[59] Print-on-demand vendors use the digital file from the publisher and print books in a variety of formats, paper, color, and bindings. Authors who publish with the Rice University Press will submit works under the Creative Commons copyright policy, offering nonexclusive rights to the press to publish the work while allowing others to reuse the material under terms the authors specify.^[60] Scholarly monographs can be published in the open with normal editorial review at less expense as digital products with print-on-demand available. In this manner, digital books may allow book-oriented disciplines to communicate more effectively with larger audiences than in paper-only formats.

LONG-TERM STORAGE AND RETRIEVAL

Scholarly publishing includes a commitment to long-term storage and retrieval so that the work of today's authors can influence the work of future generations. Works printed on acid-free paper, kept in climate-controlled conditions, and not subjected to vandalism can be used for hundreds of years. Libraries owned the physical artifacts and could maintain storage and access as long as the library maintained its facility. Digital products, in contrast, are often inherently volatile and rely on machines for use that quickly obsolesce. In addition, libraries sometimes license access to digital products. Under some contracts, the library loses all access when it stops paying the license fees and long-term access depends on the viability of the vendor rather than on the library.

The advantage of digital storage is that remote access is as convenient as local and therefore the cost of fixed long-term storage can be widely shared. William G. Bowen, President of the Andrew W. Mellon foundation, led the launch of JSTOR in 1995 to capitalize on this opportunity. Now a freestanding, not-for-profit, JSTOR seeks

permission from publishers to digitize page images and create full-text files of the complete historic runs of journals. It then licenses access to libraries to its digital collection, with an embargo on recent years as stipulated by each publisher. Libraries pay an initial capital fee and a continuing annual license for access to more than 900 journals from 450 publishers in 2007 with more expected.^[61] In 2007, 1900 libraries in the United States and its possessions and a similar number in 122 other countries subscribed to JSTOR, including academic, school, and other types of libraries. EBSCO and similar database integrators provide similar de facto shared digital storage services for their collections. JSTOR and similar organizations store their files at multiple sites, maintain off-site copies, and use formats that can more easily migrate to future technologies.

Long-term archiving of open access materials is another step. JSTOR is essentially a subscription service for storing and retrieving materials also originally published and paid for by subscription by libraries. One of JSTOR's criteria for deciding to include a journal in its collection is the number of institutional subscribers to a journal. Libraries justify participation in JSTOR, in part, on the ability to substitute a license to a remote digital archive for building more space to store old print journals. Open access journals do not involve library subscriptions and require no storage space. Will libraries pay for long-term archival storage of materials that are readily available without charge today on the Internet? Libraries have often purchased reprints and microform collections of historic materials. Library subscriptions to back files of open access journals seem well within the scope of traditional library collections just as JSTOR licenses sustain back files. Intellectually valuable open access publications are then likely to endure as part of library collections based on library license fees just as digital archives of subscription journals will. The Portico, spun off by JSTOR in 2005, archived 1.8 million articles by 2007 with funding from publishers and libraries.^[62]

FRONTIERS

For scholarly journals, there are several frontiers at play between subscription and open publication. One frontier is the launch of new journals. A group of scholars or a publisher who intends to launch a new journal will decide whether to sell it by subscription or to offer it in the open. If in the open, the scholars might decide to depend on the good offices of a university and philanthropy to sustain the venture, relying primarily on volunteers as editors or they might rely on author fees to generate revenue flows to compensate editors. In 2007, Blackwell Publishing, a for-profit publisher, launched its first fully open access journal, *Archives of Drug Information* with author publication fees of \$2600.^[63] The fee is \$2600 for up to 10 pages plus \$250 for each page over 10. This new publication points to

an expanding role for open journals through the launch of new journals. In contrast, the American Economic Association will launch four new journals in 2009 that will be offered by inexpensive subscriptions (Journal closings also influence the number of journals of each type. *Ulrich's Periodical Directory* lists 1679 referred academic journals as ceased; 535 of these had been available online but only 19 had been evaluated in JCR. Only 17 of the ceased journals were open access).

A second frontier arises in the selection of editors. For small-scale journals intended for specialists, an editor might serve as a volunteer, depending primarily on the good offices of his home campus. For large-scale journals that aim for wider intellectual impact that therefore must manage a larger flow of submissions, voluntary editors may not suffice. Among the distinguished scholars with the temperament and organizational skill needed to be successful editors, substantial financial inducements may be necessary to draw people into the role. Annual payment in excess of \$100,000 plus support staff may be necessary to fill demanding editorships. Substantial author fees will be necessary to support editing of such journals when they are to be open. Subscription fees may be necessary for journals with high circulation to sustain the necessary level of editorial expertise. The ability to recruit appropriate editors is an important frontier for open journals.

A third frontier, the requirement of green archiving, involves the policy of research funding agencies in requiring results to be posted in the open. As mentioned above, governments might require open publication of publicly funded research. The policy might include an embargo, might limit open publication to prepublication versions, and limit posting to institutional repositories rather than in discipline-specific databases. Leading subscription-based journal publishers, particularly those with hybrid journals, can negotiate lower author payments with longer embargoes or limit the versions and location of postings. This frontier is one of political action and contract negotiation.

A fourth frontier is the critical one of authors choosing where to publish. Authors who focus on achieving substantial reputations can choose open publications with higher expected citation rates with their highest quality works appearing in journals with significant author fees. The support of funding agencies and universities for author fees will advance this frontier. Authors may also choose subscription journals with wide circulation.^[64] For authors who publish works for narrower audiences, open journals with volunteer editors and modest or no author fees may dominate other choices.

A fifth and critical frontier is that of libraries who make decisions about support for relevant open publications and purchase of subscriptions. With modest effort, libraries can include reference to intellectually important open journals and other publications in their catalogs and other finding tools. Libraries can use their role as database integrators to include indexes that point to open materials, enhancing the frequency of use and value of open materials.

The libraries make decisions about subscriptions to databases. Some databases will be more valuable for some libraries than others in the way that a large set of medical journals is more valuable to a medical library. The better the fit of the database to a library, the more a vendor is likely to charge with database prices varying by type and size of library. The vendor will increase profit (or publisher's net in the case of not-for-profits) with prices high enough to nearly induce some libraries not to subscribe. For large databases taken to be very significant for a given category of library, the subscription rates can be quite large. The greater the extent and quality of open access alternatives, the more easily some libraries may choose not to subscribe. For smaller libraries and those for which a given database is less relevant, the vendor will offer lower prices in part because the library is more likely to find a given set of open materials to be sufficient. The vendors, in turn, seek to bundle materials into larger databases and to offer unique features to make their offerings more compelling. Open posting in institutional repositories with short embargoes narrow differences in service available in the open compared to the subscriptions.

A sixth frontier is that of readers in choosing to use open publications more often than subscription publications. Even on well-supported campuses, however, readers may turn first to open indexes and link more readily to digital full-text materials published in the open. As readers, for whatever reason, give precedence to open materials, authors, editors, publishers, and libraries will move toward open journals. Readers' willingness to tolerate advertising will also have influence. In 2007, conventional subscription journals hold sway.^[65] Scholars invest in building their reputations by publishing in highly regarded journals. Most take the traditional system of subscription journals as given in deciding where to publish and this behavior gives existing patterns inertia.

The speed of development of open publication will vary across disciplines because these frontiers will differ. Disciplines with high levels of research funding, those where more new journals are being launched, where volunteer editors are more common, where authors accept publication fees more readily, and where library support is not as deep, are likely to move to open publication faster. Where high levels of editing produce polished publications that reach wide audiences subscriptions are more likely.

THE KNOWLEDGE BASE

The intellectual success and economic viability of open access archives, journals, and indexes creates the possibility of a universal, open access knowledge database, an intellectual commons.^[66] The knowledge base could be universal in the sense of encompassing all disciplines, in being accessible to everyone on the Internet, and expanding with media beyond black text on white pages.

As a large and increasing proportion of the workforce are college graduates, universal access to the knowledge base will make it more valuable. As countries around the world make larger commitments to higher education, scholarship will play a larger role in economic growth everywhere. Scholarship, when it is available in the open, will have more value than in the past.

The tragedy of the commons, the loss of value from congestion—making it more difficult to identify the most important ideas, exploitation—pressing volunteers to undertake unreasonable efforts, and pollution—an overflow of extraneous materials, points to limitations of overreliance on sharing. The market place for ideas where intellectual property has dollar value can be an antidote to the excesses of the commons. Market forces focus effort on more important ideas, reward leading scholars who invest in becoming editors who promote the work of others, and encourage scholars to develop teaching materials and to put scholarship in forms useful beyond academia. Scholarship has value in training a more capable workforce and a better-informed citizenry. Subscription services may have particular value with high levels of editorial service, more structured and precise searching, and long-term archiving. Financial incentives tied to intellectual property from reputation, copyrights, and patents channel scholarly effort to more valuable roles in ways that may be difficult to achieve simply by sharing.

On the other hand, markets are seldom perfect. They can be frozen by monopoly. They can be overheated by pointless arms races. Dollars can give misleading signals of value. A report in 2007 by Ithaka, a not-for-profit committed to promoting innovation in higher education, urges an active role for universities and not-for-profits in developing digital publishing services.^[67] It calls for new publishing models to offer immediate access, dynamically updated materials, and collaborative environments with a broad range of digital materials. New investments will be needed to support more sophisticated publishing operations. The extent to which universities and philanthropy will decide to support such ventures will influence whether such developments will be under not-for-profit and university control. Finally, by the nature of their investments, the universities will determine the extent of open access scholarly publishing.

Open Archival Information System (OAIS) Reference Model

Christopher A. Lee

*School of Information and Library Science, University of North Carolina at Chapel Hill,
Chapel Hill, North Carolina, U.S.A.*

Abstract

The Reference Model for an Open Archival Information System (OAIS) describes components and services required to develop and maintain archives, in order to support long-term access to and understanding of the information in those archives. This entry discusses the context in which the OAIS was initiated and provides a chronology of the OAIS development process, including its transformation from a space data standard into a document of much wider scope. The author explains the nature of reference models as a particular type of standard, and then describes the major components and concepts of the OAIS Reference Model. The primary mechanisms that the Reference Model uses to convey the aspects of an OAIS are its functional model and information model. The entry also summarizes numerous (completed, ongoing, and emerging) initiatives that have adopted and expanded on the OAIS. Finally, the author discusses major implications of the OAIS.

INTRODUCTION

The Reference Model for an Open Archival Information System (OAIS) describes components and services required to develop and maintain archives, in order to support long-term access to and understanding of the information in those archives.^[1] The development of the OAIS took place within a standards development organization called the Consultative Committee for Space Data Systems (CCSDS), whose formal purview is the work of space agencies, but the effort reached far beyond the traditional CCSDS interests and stakeholders.^[2] It has become a fundamental component of digital archive research and development in a variety of disciplines and sectors.

This entry discusses the context in which the OAIS was initiated and provides a chronology of the OAIS development process, including its transformation from a space data standard into a document of much wider scope. It then describes the major components and concepts of the OAIS Reference Model. The entry also summarizes numerous initiatives that have adopted and expanded on the OAIS. Finally, the author discusses major implications of the OAIS.

HISTORICAL CONTEXT

Digital preservation has long been an area of concern for those responsible for repositories of digital objects. Data mismanagement, technological dependency, media degradation, and technological obsolescence have all threatened the long-term accessibility of resources stored in digital formats. In the 1950s, 1960s, and 1970s, organizations

began increasingly to rely on collections of computer-dependent data. Several streams of activity gradually emerged to address parts of the digital preservation problem (e.g., care and physical properties of physical storage media; hardware and software interoperability; management and provision of access to digital library collections), but there was often little communication or coordination across the streams. The streams of activity often developed their own distinct forums (journals, conferences, consortia) and sets of funding mechanisms (government budget areas, research agendas, foundation support).

Two trends that began in the 1960s and 1970s, but became much more prominent during the 1980s and early 1990s, were: 1) actors with long traditions of preserving physical artifacts (e.g., archivists, librarians, museum curators) increasingly recognizing that information which fell within the scope of their responsibility was now digital; and 2) actors with long traditions of managing computer-dependent data sets (e.g., scientific data center personnel, corporate information technology managers) increasingly recognizing that information which fell within the scope of their responsibility had long-term preservation value. The effort to develop the OAIS came at a time when the separate streams of activity were making important progress but they were only beginning to identify points of intersection between the streams. During the years immediately preceding and throughout the OAIS development effort, participants in digital preservation work increasingly recognized that they were addressing similar issues.

The 1990s were characterized by a broadening societal awareness of both the importance of standards in supporting the infrastructure that underlies various activities and the challenges of long-term digital preservation. Two

closely connected factors were the development of widely distributed computer networks and an industry trend toward commercial off-the-shelf (COTS) equipment. Rather than depending on the compatibility of an entire suite of hardware and software from a single vendor, producers and consumers of computer equipment came to rely on conventions for interchange of data between a heterogeneous set of components. Both the International Organization for Standardization (ISO) and Internet Engineering Task Force (IETF) developed layered architectures to which hardware and software producers could conform in order to ensure that their products could interchange data with other products on the Internet. In the early 1990s, the adoption of the World Wide Web reflected and contributed to a dramatic growth in the base of consumers who had a stake in the interchange of data over computer networks. The Year 2000 (Y2K) conversion effort was one widely recognized example of dependence on a widespread assortment of hardware and software components that usually interoperated in ways invisible to most people, but could cause significant problems when they failed to interoperate. In 1994, the Commission on Preservation and Access (CPA) and Research Libraries Group (RLG) created a Task Force on Digital Archiving. The Task Force issued a report in 1996 called *Preserving Digital Information*, which was frequently cited by subsequent literature on digital preservation.^[3] Two works that brought digital preservation to popular attention were a 1995 article by Jeff Rothenberg in *Scientific American* called “Ensuring the longevity of digital documents”^[4] and a movie called *Into the Future*,^[5] which was released in 1997 and shown on Public Broadcasting Service (PBS) across the United States in 1998.

Prior to the development of the OAIS, there had been numerous calls in professional literature for both development and adoption of open standards in support of long-term digital preservation. The most active standardization and consensus was associated with physical storage media and storage conditions. In other areas of digital preservation, most of the existing standards had served primarily to advance work within specific streams of activities, rather than spanning multiple professions.

OAIS DEVELOPMENT PROCESS

The historical context discussed in the previous section is essential to understanding the character and impact of the OAIS. The Reference Model was both a product of and an influential factor in the evolution of digital preservation activities in the mid- to late-1990s—reflecting preexisting notions and helping to define new notions. A major factor in the success of the OAIS was the timing of its development. Actors within several streams of activity related to digital preservation perceived the need for a high-level model but had not themselves developed one. At the same

time, several actors now felt they had knowledge from their own recent digital archiving efforts, which could inform the development of the OAIS. Despite this growing body of practical experience and understanding of the functions associated with digital archiving, one essential element that was missing was a common vocabulary. Problems had often stemmed from terms—such as archives/archiving or metadata—that were used so widely and for so many different purposes that it was difficult to determine if they were being used in the same way by different actors. The combination of pressing need, available expertise, and inconsistent language meant the time was ripe for developing a reference model that could codify and support greater consistency in discussions of digital archives.

The development of the OAIS took place within the CCSDS, whose formal purview was specifically support for study of the terrestrial and space environments. However, the OAIS development effort took on a much wider scope than one may have reasonably predicted, given its CCSDS origins. The OAIS development process ultimately involved and gained visibility among a much broader set of stakeholders than simply members of the CCSDS. The word “Open” in the acronym OAIS—meant to indicate that the standard was “developed in open forums”—was a defining feature of its evolution. The leader of the OAIS development process was Don Sawyer, Computer Scientist and head of the U.S. National Aeronautics and Space Administration (NASA) Office of Standards and Technology (NOST) at the Goddard Space Flight Center (GSFC) in Greenbelt, Maryland. Sawyer indicated early and continued to reiterate that the process should be open and inclusive, in order to get sufficient input and buy-in. The core development team actively recruited commentary on the drafts of the document and gave dozens of public presentations about the Reference Model to a diverse range of professional groups.

The formal process began on April 5, 1994, when Gael Squibb of the Jet Propulsion Laboratory (JPL) proposed a New Work Item (NWI) related to “archiving space data” to ISO Technical Committee 20 (Aircraft and Space Vehicles), Subcommittee 14 (Space Systems and Operations). This proposal ultimately found a home in another subcommittee of ISO TC 20: Subcommittee 13 (Space Data and Information Transfer Systems). The formal Secretariat for TC 20/SC 13 is the American National Standards Institute (ANSI), and it is administered by NASA. The CCSDS is a liaison organization to TC 20/SC 13 (see Fig. 1). Sawyer made the case for this effort to NASA management. As the NASA representative, Sawyer also submitted a document to Panel 2 (Information Interchange Processes) of the CCSDS on April 25, 1995, proposing a new “work package.” In May, Panel 2 created “WP [Work Package] 700 Archiving” with Sawyer as the leader and the initial subtask being “WP 710 Archiving Reference Model.” Sawyer and Lou Reich, who worked under contract for

Fig. 1 Organizational context of OAIS development.

Source: Adapted from C. Lee, *Defining Digital Preservation Work: A Case Study of the Development of the Reference model for an Open Archival Information System*. Doctoral Dissertation, University of Michigan: Michigan, 2005.^[2] CCSDS, Consultative Committee for Space Data Systems; GSFC, Goddard Space Flight Center; ISO, International Organization for Standardization; NASA, U.S. National Aeronautics and Space Administration; NOST, NASA Office of Standards and Technology.

the GSFC as Senior Consulting Engineer for the Computer Sciences Corporation, coauthored a preliminary discussion draft of a reference model document. Sawyer and Reich remained the primary authors and editors of later versions, but the process also increasingly drew from contributions (both text and figures) from other participants. John Garrett, who was a contractor for the NSSDC as Senior Analyst at Hughes STX (ST Systems Corporation), helped to set up the initial meeting, and he served as a significant source of administrative support and documentation throughout the OAIS development process.

Development of the OAIS was markedly different from the previous standards development efforts of the CCSDS by being both broader in scope and inclusive of a more diverse set of actors. In order to support this unusually inclusive effort, the leaders set up a unique meeting and decision-making structure. In addition to the well-established semiannual CCSDS meetings, the OAIS development effort also involved a set of 18 U.S. Workshops, devoted primarily to document development, and a set of more open meetings (one in France, two in the United Kingdom, and two in the United States), designed to gather input and review from a wider set of actors. Most of the U.S. Workshops took place at the Archives II facility of the U.S. National Archives and Records Administration (NARA); Bruce Ambacher, Archives Specialist at NARA, was one of the most active participants in the

OAIS development process. The creation of the Reference Model involved a relatively small and stable set of core actors, but it also involved a much larger set of actors who had more limited Workshop participation. The latter played an extremely important role in the development, review, and visibility of the Reference Model. There were 306 individuals who participated in one or more of the Workshops.

Development of the OAIS involved negotiation over issues such as the scope of the Reference Model, its intended purpose, and the definition of basic terms. The development process also involved considerable borrowing and adaptation of ideas and documents already in existence. Over time, common notions about the content of the Reference Model became more established, and the number and extent of revisions to drafts of the Reference Model decreased.

After being requested to do so by CCSDS Panel 2, ISO SC 13 voted on May 22, 2000 to allow circulation of Red Book 1^[6] as a Draft International Standard (DIS) to all ISO national member bodies. By releasing the Reference Model as a Red Book, the CCSDS was indicating that the document was “technically mature and ready for extensive and formal review by appropriate technical organizations within each Member Agency.” Comments received in response to Red Book 1 implied substantive changes to the document. SC 13 sent a request to the ISO in January

2001 to “reprocess” the DIS, meaning a revised document would be resubmitted to ISO member bodies for another vote. Red Book 1.1 (April 20, 2001), Red Book 1.2 (June 2001), and Red Book 2 (July 2001) were the result of efforts to address the comments received in response to Red Book 1. On October 23, 2001, SC 13 approved the submission of Red Book 2 for ISO vote. There were then a few minor editorial changes to the document before it was circulated (as the Blue Book)^[6] to ISO member bodies for balloting. A Blue Book is a CCSDS Recommendation, which “reflects resolution of official comments from Member Agencies during formal reviews, and, as such, represents the consensus of appropriate implementing organizations within each Member Agency. Member Agency approval of a Blue Book implies an intent to reflect its provisions in future data systems standards developed through internal mechanisms.” The ISO balloting process, which involved ISO national member bodies, ran from January 24 to April 5, 2002. There were eight affirmative votes, no negative votes, and two abstentions. The chair of SC 13 formally reported the results of voting on the Reference Model to ISO on August 20, 2002. On February 24, 2003, the Reference Model was finally published by ISO as an International Standard (ISO 14721:2003).^[7] The Blue Book version, which is freely available from the CCSDS Web site, is identical in content to the International Standard, except that the current Blue Book version reflects a September 2007 “editorial correction,” involving slight alterations to several figures to correct “display anomalies” (problems with encoding of line breaks had resulted in extraneous square blocks appearing next to some text elements) and a “typographical error” in one of the figures.

Many important activities in the development of the OAIS took place outside the context of formal ISO Archiving meetings and review processes. Teleconferencing, e-mail, and the Web greatly facilitated work on the OAIS and allowed review and use of the Reference Model drafts by those who were not necessarily able to attend the Workshops. Core members of the OAIS development effort gave dozens of presentations related to the Reference Model at conferences and other professional events. Several of the actors in the ISO Archiving Workshops also took part in mass storage systems and technologies (MSST) conferences, which served as forums for both the dissemination of information about the development of the Reference Model and recruitment of actors into the process. Individuals and organizations involved in initiatives that attempted to apply and test the Reference Model—e.g., CEDARS (CURL [Consortium of Research Libraries] Exemplars in Digital Archives) in the United Kingdom, NEDLIB (Networked European Deposit Library), British Library, and PANDORA (Preserving and Accessing Networked Documentary Resources of Australia)—played an essential role in the process. The archives certification work that built off of the Reference

Model also provided important input into the development of the OAIS and demonstrated the Reference Model’s potential value to a variety of stakeholders.

Development of the Reference Model drew from many other sources. These included concepts, terminology, models, and strings of text and images from guidelines, reports, and standards. In some cases—such as the “Z39.50 profile for access to digital collections” (PDC),^[8] *Preserving Digital Information, Planetary Data System Data Preparation Workbook*,^[9] and *IEEE Guide to the POSIX Open System Environment (OSE)*^[10]—it is possible to identify specific terms or concepts that were incorporated into the Reference Model. Other sources were discussed during Workshops and provided varying degrees of conceptual background for the work on the Reference Model.

OAIS AS A REFERENCE MODEL

The OAIS is a reference model, which is a very particular type of standard. Carl Cargill provides a framework for describing standards, which distinguishes providers of information technology products and services from the users of those products and services. According to Cargill, these two groups have very different motivations and needs in the standardization process.

On the provider side is the global model that describes all of the potentials that the IT industry will need to satisfy all users over a long time in nearly all situations, and that serves as a reference for all providers. This reference model, if it is correctly constructed, includes some present and future technologies, a road map function, and some of the methodologies of the thought processes that occurred when it was constructed. The time span covered is up to ten years, and the model is applicable to all technical disciplines that deal in this area. On the IT user side is a description of a solution implementation that is immediate and particular to that user’s application problems (p. 1-11).^[11]

As explained by Cargill above, reference models operate at a higher level of abstraction than other types of standards and are purposely designed to be “implementation-independent.” The OAIS itself provides the following definition of reference model:

A framework for understanding significant relationships among the entities of some environment, and for the development of consistent standards or specifications supporting that environment. A reference model is based on a small number of unifying concepts and may be used as a basis for education and explaining standards to a nonspecialist.^[11]

Cargill explains that bridging the gap between reference models and application implementations requires a chain

of standards at increasing levels of specificity (p. 1-12).^[1] Within the arena of digital archives, this means that one would expect more specific standards to emerge, which indicate how to apply the concepts of the OAIS in more specific contexts. As explained later in the section on “OAIS Adoption, Extension, and Future Directions,” such follow-on standardization has been taking place.

CONTENT OF THE OAIS

The OAIS is a 148-page document, composed of six sections and six annexes. Section 1 frames the content to follow, by providing discussions of purpose, scope, applicability, definitions, rationale, and conformance requirements. It also situates the document in a larger context by including a “road map for development of related standards.” Section 2 lays out several core concepts that are then modeled in more detail in Section 4. These include archive; information (as distinct from data); interfaces between an archive, Producers, Consumers, and Management; and Information Package and its subtypes: Submission Information Package (SIP), Archival Information Package (AIP), and Dissemination Information Package (DIP). Section 3 discusses the responsibilities of an Open Archival Information System and “some examples of mechanisms to discharge these responsibilities.” Section 4 presents a “more detailed model view” of the concepts previously laid out in the document. The section includes a functional model (including a high-level view and then unpacking of each entity and data flows between the entities) and an information model, which provides a hierarchical set of views and explanations for what logical elements should be stored and managed in association with a data object. Section 4 also provides an account of the “transformations, both logical and physical, of the Information Package and its associated objects as they follow a lifecycle from the Producer to the OAIS, and from the OAIS to the Consumer.” Section 5 provides some discussion—intended to be implementation agnostic—of technical issues and strategies that an archive can potentially use to address changes in underlying hardware, software, formats, and access services. Section 6 discusses potential arrangements between multiple archives. The annexes that follow Section 6 are not considered part of the Reference Model’s normative content but are instead “provided for the convenience of the reader.” The annexes include a set of five “scenarios” that use OAIS terminology and concepts to describe specific existing archives; explanations of how the Reference Model relates to other standards and projects; a brief Unified Modeling Language (UML) tutorial; list of references; a layered model of how software could be used to support Representation Information; and a “composite diagram” that presents in one place the detailed interfaces between each of the entities in the functional model.

Fundamental Terms and Concepts

The Reference Model defines an OAIS as “an archive, consisting of an organization of people and systems, that has accepted the responsibility to preserve information and make it available for a Designated Community.” Many of the requirements for an OAIS are based on the needs of its Designated Community, which is the set of one or more “user communities” that the OAIS is serving. An OAIS is responsible for digital information over the “long term,” which is “long enough to be concerned with the impacts of changing technologies, including support for new media and data formats, or with a changing user community” (p. 1-11).^[1] One of the fundamental challenges of an OAIS is to ensure that the digital information in its care is “independently understandable” to the Designated Community, which means that the Designated Community can understand it “without having to resort to special resources not widely available, including named individuals” (p. 1-10).^[1] The Designated Community has a certain “knowledge base,” which can change over time.

One of the most important insights embedded in the Reference Model is that the “Content Information” to be preserved by an archive is composed not only of a “set of bit sequences” (the “data object”) but also associated sufficient “Representation Information” to allow the bits to be rendered, used, and understood.

Since a key purpose of an OAIS is to preserve information for a Designated Community, the OAIS must understand the Knowledge Base of its Designated Community to understand the minimum Representation Information that must be maintained. The OAIS should then make a decision between maintaining the minimum Representation Information needed for its Designated Community, or maintaining a larger amount of Representation Information that may allow understanding by a larger Consumer community with a less specialized Knowledge Base. Over time, evolution of the Designated Community’s Knowledge Base may require updates to the Representation Information to ensure continued understanding (p. 2-4).^[1]

The three main roles played by the external entities with which an OAIS interacts are Producer, Consumer, and Management. Producers are “persons, or client systems, who provide the information to be preserved.” Consumers are “persons, or client systems, who interact with OAIS services to find preserved information of interest and to access that information in detail.” Management is “the role played by those who set overall OAIS policy as one component in a broader policy domain (p. 1-11).”^[1]

A diversity of workflow and collaborative arrangements can be mapped to the Reference Model by representing “other OAISs” and “internal OAIS persons or systems” as Producers and Consumers (pp. 1-8, 1-12).^[1] The Reference Model describes “four categories of archive association” based on “successively higher degrees of interaction”:

- Independent—“no management or technical interaction.”
- Cooperating—“potential common producers, common submission standards, and common dissemination standards, but no common finding aids.”
- Federated—serve “both a Local Community (i.e., the original Designated Community served by the archive) and a Global community (i.e., an extended Designated Community) which has interests in the holdings of several OAIS archives and has influenced those archives to provide access to their holdings via one or more common finding aids.”
- Shared resources—have agreed to share resources between the archives, which “requires various standards internal to the archive (such as ingest-storage and access-storage interface standards), but does not alter the user community’s view of the archive” (p. 6–2).^[1]

The primary mechanisms that the Reference Model uses to convey the aspects of an OAIS are its functional model and information model. Roughly speaking, the former indicates what an OAIS must do, and the latter indicates what the OAIS must have in its collections.

Functional Model

The functional model is composed of seven main functional entities and the interfaces between them: Access, Administration, Archival storage, Common Services, Data Management, Ingest, and Preservation Planning. The single figure from the Reference Model that has received the most attention in the digital preservation literature is a representation of six of the functional entities (see Fig. 2). Not directly represented in Fig. 2 are Common Services,

which are the “supporting services” that must be in place for computer systems to operate and perform properly, including interprocess communication, name services, temporary storage allocation, exception handling, backup, directory services, as well as other aspects of operating system, network, and security services. Although Common Services are necessary for an OAIS, they are not a major focus of the Reference Model, because they are “assumed to be available” (p. 4–2).^[1] As illustrated in Fig. 2, the OAIS functional model also identifies between Administration and management, but it does not elaborate any function within management itself.

Many aspects of the functional model rest on the distinction between SIPs, AIPs, and DIPs. SIPs are what the OAIS receives from Producers. AIPs are what the OAIS manages and preserves. DIPs are “derived from one or more AIPs, [and are] received by the Consumer in response to a request to the OAIS” (p. 1–10).^[1]

Ingest is the entity that receives SIPs, performs quality assurance on the SIPs, generates AIPs, extracts Descriptive Information from AIPs, and coordinates updates to Archival Storage and Data Management. Archival Storage is responsible for “receiving AIPs from Ingest and adding them to permanent storage, managing the storage hierarchy, refreshing the media on which archive holdings are stored, performing routine and special error checking, providing disaster recovery capabilities, and providing AIPs to access to fulfill orders” (pp. 4–1, 4–2).^[1] Data Management supports the populating, maintenance and accessing of both Descriptive Information and administrative data associated with the OAIS holdings; this includes database administration, database updates, performing queries on the data, and producing reports that result from the queries. Administration is responsible for “the overall

Fig. 2 OAIS Functional Entities.

operation of the archive system,” which includes soliciting and negotiating submission agreements, auditing submissions, configuration management, system engineering, activating stored requests, and the establishment and maintenance of standards and policies (p. 4–2).^[1] Preservation Planning monitors the environment for important changes in technology or the needs of the Designated Community; evaluates the implications of those changes to the archive’s holdings; designs Information Package templates; “provides design assistance and review to specialize these templates into SIPs and AIPs for specific submissions”; “develops detailed Migration plans, software prototypes and test plans,” and provides periodic recommendations for “archival information updates,” standards and policies (p. 4–2).^[1] Access both provides and appropriately restricts Consumers’ ability to discover, request, and receive information from the archive, including DIPs, “result sets” and reports (p. 4–2).^[1]

Information Model

The information model defines and describes “the types of information that are exchanged and managed within the OAIS” (p. 4–18).^[1] It is based on the recognition that

long-term preservation of digital information requires an archive to “store significantly more than the contents of the object it is expected to preserve” (p. 4–19).^[1] The Reference Model uses the term “Information Package” to refer to the logical unit that includes both a digital object and the other types of information that should be associated with the digital object in order to preserve and provide meaningful access to it over time. AIPs are the information packages that are managed internally by the OAIS. An AIP can be either an Archival Information Collection (AIC), “whose Content Information is an aggregation of other Archival Information Packages” (p. 1–7),^[1] or Archival Information Unit (AIU) “whose Content Information is not further broken down into other Content Information components.”^[24] Fig. 3 presents the main types of information that constitute and are associated with an AIP. The Package Description is information about an Information Package, which is used by Access Aids. An Access Aid is “a software program or document that allow[s] Consumers to locate, analyze, and order Archival Information Packages of interest” (p. 1–7).^[1] Packaging Information, in contrast, is not intended for direct use by Consumer but is instead “used to bind and identify the components of an Information Package”

Fig. 3 Archival Information Package (Detailed view).

Source: Reference Model for an Open Archival Information System (OAIS); Consultative Committee for Space Data Systems: Washington, D.C., 2002-4-37.

(e.g., volumes and directory information for the components) (p. 1–12).^[11]

The Content Information is the “the original target of preservation” (p. 1–8).^[11] As described earlier, Content Information is composed of both the Data Object (for digital information, one or more sequences of bits) and Representation Information, which “allows for the full interpretation of the data into meaningful information” (p. 4–19).^[11] Representation Information can be either Structure Information, which “imparts meaning about how other information is organized,” such as mapping “bit streams to common computer types such as characters, numbers, and pixels and aggregations of those types such as character strings and arrays” (p. 1–13),^[11] or Semantic Information, which indicates the meaning of language used in either the Structure Information or other parts of the Content Information.

Representation Information is often conveyed using Digital Objects, which then require their own Representation Information, resulting in what is called a Representation Network. For example, a string of bits (Digital Object) could represent an array of pixels, but a Consumer would also need information about the file format (Representation Information), in order to render and use that Digital Object as an image. If the image were encoded using Scalable Vector Graphics (SVG), which is based on Extensible Markup Language (XML), then rendering and using the image would require not only the SVG specification but also the specification for XML, as well as other specifications for character encoding and Uniform Resource Identifiers (URIs) upon which XML itself depends.

As illustrated in Fig. 3, Content Information is “further described by” Preservation Description Information (PDI), which “is necessary for adequate preservation of the Content Information.” PDI is composed of:

- Reference Information—“identifies, and if necessary describes, one or more mechanisms used to provide assigned identifiers for the Content Information” and “provides identifiers that allow outside systems to refer, unambiguously, to a particular Content Information.”^[13]
- Provenance Information—“origin or source of the Content Information, any changes that may have taken place since it was originated, and who has had custody of it since it was originated” (p. 1–12).^[11]
- Context Information—“documents the relationships of the Content Information to its environment” including “why the Content Information was created and how it relates to other Content Information objects” (p. 1–8).^[11]
- Fixity Information—“documents the authentication mechanisms and provides authentication keys to ensure that the Content Information object has not been altered in an undocumented manner” (p. 1–10).^[11]

PDI is an extension and elaboration of what *Preserving Digital Information* called the “features that determine

information integrity and deserve attention for archival purposes”: “content, fixity, reference, provenance, and context.”^[12]

OAIS ADOPTION, EXTENSIONS, AND FUTURE DIRECTIONS

Several years before it had reached formally approved status within the CCSDS or ISO, the OAIS was already receiving considerable attention from those engaged in digital preservation research and development. An extensive survey of the English-language literature up to April 2005 identified 335 sources that cite or discuss the OAIS, beginning in 1997 and increasing every year thereafter.^[13] Over the past several years, the OAIS has come to be a widely assumed basis for research and development on digital archives, with conference papers, articles, and reports very often presenting their findings within the context of the OAIS.

The OAIS has become “the reference model of choice of those involved in digital preservation worldwide,”^[14] serving as a “galvanizing force”^[15] and a “major factor in the advancement of digital archiving efforts.”^[16] It has contributed “a common language and concepts for different professional groups involved in digital preservation and developing archiving systems.”^[17] “The reference model represented common ground upon which to consolidate understanding of the needs and requirements of digital preservation: an opportunity to gather the strands of isolated digital preservation activities, merging them into a shared (albeit highly conceptual) characterization of the problem’s boundaries.”^[18]

A large number of research and development projects have either based their work directly on or claimed that their final products conform to the OAIS, many of which are listed in Table 1.

Professional development has also been strongly influenced by the OAIS. One of the earliest activities of the Digital Preservation Coalition (DPC) in the United Kingdom after its formation in 2001 was to develop, along with the British National Space Centre (BNSC), a seminar to discuss and “raise the profile of” the OAIS. The Cornell University Library offered a highly acclaimed workshop series from 2003 to 2006, and disseminated an associated tutorial, both called Digital Preservation Management: Implementing Short-Term Strategies for Long-Term Problems, which used the OAIS as a foundation.^[19] In 2008, Inter-University Consortium for Political and Social Research (ICPSR) became the host of the Digital Preservation Management workshop and tutorial, which continue to be based heavily on the OAIS.

From its initial conception, the OAIS was intended to serve as the basis for further development of more specific digital archives standards, and the OAIS has indeed played that role. It has served as the basis for several very prominent digital preservation metadata initiatives, including

Table 1 Examples of research and development activities with stated OAIS influence or requirements.

CEDARS, NEDLIB, and two joint Research Libraries Group (RLG)/Online Computer Library Center (OCLC) efforts—the Working Group on Preservation Metadata and then the Preservation Metadata Implementation Strategies (PREMIS) Working Group. The CCSDS also has been coordinating the development of follow-on standards based on the OAIS, which provide more detailed guidance related to parts of the OAIS functional and information models. The *Producer–Archive Interface Methodology Abstract Standard* (PAIMAS) “defines the methodology for the structure of actions that are required from the initial time of contact between the producer and the archive until the objects of information are received and validated by the archive.”^[20] PAIMAS was issued as a CCSDS Blue Book in May 2004 and was published as an ISO standard (ISO 20652) in 2006.^[21] The *Producer–Archive Interface Specification* (PAIS) focuses on an even finer level of granulating, by presenting “a standard method to formally define the digital information objects to be transferred by an information Producer to an Archive and for effectively transferring these objects in the form of Submission Information Packages (SIPs).” As of the writing of this entry, the PAIS

was in a tenth White Book version (April 2009), undergoing consideration for Red Book status. A White Book is “a preliminary draft of a planned CCSDS Recommendation or Report” that is “under development” and “not necessarily endorsed by any CCSDS Member or Observer Agency or given any CCSDS external distribution.”^[22]

RLG and NARA formed a Digital Repository Certification Task Force, whose efforts were explicitly tied to the OAIS. An initiative by the Center for Research Libraries (CRL) is extending the RLG/NARA certification work, with funding from the Andrew W. Mellon Foundation. A Birds of a Feather group is also attempting to develop an ISO standard for digital repository audit and certification, through the same channels as the OAIS, viz. ISO TC 20, SC 13, and the CCSDS.

The OAIS is currently undergoing a 5-years review within the CCSDS and then within the ISO. During the comment period, which ended in October 2006, the CCSDS received 11 separate documents containing comments. At a meeting on October 4, 2007, the Digital Archive Ingest (DAI) Working Group began reviewing the OAIS review comments, and identified several action

items related to specific parts of the text. In 2003, the CCSDS underwent a major reorganization. The digital archives standardization activities that were previously part of Panel 2, including the OAIS, were moved into a new area called Mission Operations and Information Management Services (MOIMS). The DAI working group, is part of MOIMS. The DAI Working Group determined an initial set of responses to the comments, shared the potential responses with those who submitted the original comments, and then revised the OAIS document based on the comments and follow-on interchanges. On May 5, 2009, John Garrett (Chair) and David Giaretta (Deputy Chair) of the DAI Working Group disseminated a proposed draft of the revised OAIS Reference Model through several electronic mailing lists, “seeking primarily to identify errors” in preparation for submitting the revised Reference Model for ISO review and balloting.

CONCLUSION

The OAIS has been a focal point and foundation for discussion of digital preservation and digital curation across many professional boundaries. It is thus valuable for information professionals not only to understand the content of the document but also to learn lessons about how the Reference Model was developed and promulgated. A reference model is a very high-level, conceptual standard. Rather than providing detailed specifications of mandatory data elements or file formats, the OAIS has introduced a set of interrelated terms and concepts. Its development occurred during a period when many professional communities had a need for such a high-level standard but had not yet developed one themselves. There are various ways in which the Reference Model is able to provide detailed concepts, while still remaining relatively “implementation-independent”: presentation of the functional model and information model in terms of high-level entities; extensive use of figures; and elaboration of implementation details in nonnormative appendices to the document, including several organization-specific “scenarios.”

Much of the value of the Reference Model comes from its coherence, clarity, and synthesis of ideas. The Reference Model does define many new terms and introduces many original concepts, but its development has also been characterized by significant adaptation and reuse of preexisting sources.

Finally, the word “Open” in the acronym OAIS—meant to indicate that the standard was “developed in open forums”—was a defining feature of its evolution. The leaders of the effort presented draft products to many professional forums and actively recruited contributions and commentary. In addition to the traditional set of CCSDS stakeholders (space agencies and their contractors), many other organizations and individuals also contributed to the OAIS development process.

The OAIS is playing a major role in many current standardization, research, and development initiatives. Its impact on professional conversations surrounding digital preservation and digital curation continues to grow, 7 years after the Reference Model was approved as an International Standard.

ACKNOWLEDGMENTS

The author would like to thank Don Sawyer for sharing information about the OAIS five-year review process and the CCSDS for granting rights to use two of the figures from the OAIS.

Open Source Software

Michael Tiemann

Open Source Initiative, Chapel Hill, North Carolina, U.S.A.

Abstract

Open Source software is distinguished not by programming language, operating environment, nor application domain, but rather by the license(s) that governs the use, distribution, and, most importantly, the rights to access and modify the software's source code. Together, software source code and open source licensing have dramatically changed many conventional assumptions about software and the software industry itself.

Open Source software is an important^[1,2] and growing^[3] class of software. Open Source software is distinguished not by programming language, operating environment, nor application domain, but rather by the license(s) that governs the use, distribution, and, most importantly, the rights to access and modify the software's source code. Together, software source code and open source licensing have dramatically changed many conventional assumptions about software and the software industry itself.

As of early 2009 there are roughly 70^[4] licenses that are officially recognized as Open Source Licenses. These licenses govern software that spans the software gamut from operating systems (like Linux) and compilers (like GCC and G++) to Web servers and clients (like Apache and Firefox) to leading applications and technologies in bioinformatics, statistical display and analysis, 2-D and 3-D paint, illustration and animation software, databases, content management, customer relationship management, accounting, and geographic information systems. And even these categories encompass but a few of the 10,000 + open source software packages that are freely available for major Linux distributions such as Fedora,^[5] Ubuntu,^[6] and Red Hat Enterprise Linux.^[7] In 2004 it was estimated that the Linux kernel, if it were to be developed using proprietary methods and private investment, would have cost more than \$600M to create, and that the roughly 1000 packages typical in Linux distributions of the time would have cost more than \$1B.^[8] In 2005 an analysis of the Debian project estimated that its 230 million lines of source code (230M SLOC) would have required 60,000 person-years of development at a cost of more than \$3B USD.^[9] But these estimates speak to the possible cost, not the real cost of developing open source (which was far lower, most likely less than 1/20 the cost of developing proprietary software, for reasons discussed later in this entry). Nor does it consider the true value of open source, which has the potential to remedy as much as \$1T USD per year in dead-loss write-offs of failed proprietary software implementations. (The \$1T per year figure is extrapolated from the statistics that worldwide ICT is expected to top \$3.4T USD in 2008^[10]

and because 18–30% of all ICT investments, predominantly based on proprietary software because that is the dominant model of the industry today, are dead-loss write-offs).^[11,12] Open source software is thus an important topic because the financial implications to the global economy are potentially large.

Before explaining what is an open source license, and thus what is open source software, we will first give a brief history of the origins of open source principles and the success of the open source software model.

The two most important precursors to the idea of open source software as a movement unto itself were the Berkeley Systems Distribution of Unix (also known as BSD Unix) and Richard Stallman's Project GNU (GNU is a recursive acronym for "GNU's Not Unix!"). Both of these projects became known to the academic and entrepreneurial communities in the early 1980s. BSD was licensed under terms that permitted users to read, modify, and redistribute the software for research or commercial purposes, but without a requirement that the source code be made freely available to all who used any product that incorporated the operating system. Sun Microsystems successfully commercialized BSD as the basis of their SunOS operating system, and Sun chose to make their version of BSD—including access to the source code—proprietary to Sun, as permitted by the BSD license. The GNU project was covered by the General Public License (GPL), which permitted users the freedom to read, modify, and share (redistribute) the software, subject to the restriction that users who distribute modified or unmodified versions of the software must also distribute the source code from which those versions were created. These two licenses, one which made source available and sharing optional, one which made source availability and sharing both mandatory as a condition of redistribution, began a long and far-reaching experiment: what licensing model is best for what type of software project, in what contexts, and for whom?

The Free Software movement, founded by Richard Stallman and defined by his *GNU Manifesto*^[13] argued

that software freedom was an ethical issue of the highest importance, and that software hoarding was an unethical activity. Some programmers were swayed by this argument and joined the Free Software Foundation or made common cause with Stallman, but many more simply enjoyed the freedoms granted by the GPL to use what they considered to be better software than any proprietary alternative. And as more software developers used GNU software, more developers also naturally contributed to it (as they were free to do). Before long, despite the fact that many did not agree with Stallman's politics, they found his software to be unimpeachable and they found that contributing their changes to the GNU project was more economical than trying to maintain those changes themselves.

At the same time, the University of California at Berkeley provided a great institutional environment for software developers to learn, contribute, make a reputation, and then join the ranks of Silicon Valley startups to make millions. By the late 1980s, Sun Microsystems was one of the most powerful and respected companies in Silicon Valley. Their key technology asset, SunOS, was based on source code that Bill Joy wrote while a graduate student at Berkeley. But the fact that Sun did not share their code freely with the community began to irk many, and there were signs that for all its power, Sun's competitive position was vulnerable to the many projects that freely shared source code could produce, including versions of BSD that others chose to work on and commercialize.

Cygnus Support was the first company to make a business providing commercial support exclusively to software whose source code was freely available. The tagline of the company was "We make free software affordable," a joke about the fact that just because something is freely available doesn't make it cheap to use or manage. Although Cygnus Support was a successful company, growing fast enough to be profiled in *FORTUNE*^[14] and earn a spot^[15,16] on the Software 500 list of the world's largest software companies before its 10th anniversary, the mainstream business press focused so much on the paradox of making money on "free" software that it never could take seriously the multimillion dollar revenue streams that Cygnus generated year after year.

Moreover, the politics of "free software" was off-putting to many would-be entrepreneurs who wanted to focus their efforts on technology and business, not freedom *per se*. Thus, while GNU software was seriously challenging the core assumptions of proprietary software advantage (that somehow secret knowledge is superior to knowledge that is widely known and shared), and while GNU software was demonstrating just as clear and positive a return on investment as companies investing in proprietary software,^[17] there was a distinct lack of critical mass around the idea of commercializing free software.

In 1997, Eric Raymond published a seminal essay, *The Cathedral and The Bazaar*.^[18] This paper attempted to

unravel how it was that a group of amateurs (doing software for the love of it), many of whom had not even met each other, could coordinate their activities and out-produce the best funded, most highly recruited programmers of Silicon Valley and the Pacific Northwest. Among the many insights in this paper, one of the most powerful (dubbed Linus's law) was the idea that the more widely available the source code is for public testing, scrutiny, and experimentation, the more rapidly all forms of bugs will be discovered. This was a remarkable repudiation of Brook's Law (discussed below), which argued that adding more developers to a late project only makes it later.^[19] In the world of software, this insight was like finding a way to travel faster than the speed of light, and the only requirement, it seemed, was to abandon the model of proprietary software development.

In 1998, a group of individuals that included both Eric Raymond and the author advocated that the term "free software" be replaced by open source software (abbreviated OSS) as an expression which is less ambiguous and more comfortable for the corporate world.^[18] In addition to creating the term "open source," the group attempted to codify the features and benefits they saw that derived from granting liberal rights with respect to software source code and software distribution. The group created the Open Source Definition (OSD)^[19] which codifies how licenses must be written to provide these rights and thus deliver the benefits. The term "open source" became immediately popular, and the Open Source movement was born (Fig. 1)

The Open Source Initiative (OSI) was founded in 1998 as a California 501(c)3 nonprofit education and advocacy group for open source software. The OSI acts as the steward of the OSD and it judges whether licenses submitted to it do or do not meet the criteria set forth in the OSD. The GNU GPL and the BSD licenses were among the first to be approved as "open source licenses," but now there are dozens and dozens that have been approved. The license approval process developed from the time-honored tradition of scientific peer review. Namely, when a new theory (or in this case, license) makes a claim (or in this case, a license asserts that it is open source), it is up to the community to study the claim and attest to its validity or point out its flaws, and it is up to some formal authority to review the community's findings and make a judgment as to whether the claim is accepted into the canon of knowledge (or in this case the list of approved licenses). This consensus-based approach has been sufficiently transparent and fair that an increasing number of national governments are adopting the OSD and the OSI's rulings as a legitimate basis for determining whether software is open source for national policy purposes.^[20]

We shall now turn our attention to the subject of software development, specifically to compare and contrast open source software development with some prominent

1. Free Redistribution

The license shall not restrict any party from selling or giving away the software as a component of an aggregate software distribution containing programs from several different sources. The license shall not require a royalty or other fee for such sale.

2. Source Code

The program must include source code, and must allow distribution in source code as well as compiled form. Where some form of a product is not distributed with source code, there must be a well-publicized means of obtaining the source code for no more than a reasonable reproduction cost preferably, downloading via the Internet without charge. The source code must be the preferred form in which a programmer would modify the program. Deliberately obfuscated source code is not allowed. Intermediate forms such as the output of a preprocessor or translator are not allowed.

3. Derived Works

The license must allow modifications and derived works, and must allow them to be distributed under the same terms as the license of the original software.

4. Integrity of The Author's Source Code

The license may restrict source-code from being distributed in modified form *only* if the license allows the distribution of "patch files" with the source code for the purpose of modifying the program at build time. The license must explicitly permit distribution of software built from modified source code. The license may require derived works to carry a different name or version number from the original software.

5. No Discrimination Against Persons or Groups

The license must not discriminate against any person or group of persons.

6. No Discrimination Against Fields of Endeavor

The license must not restrict anyone from making use of the program in a specific field of endeavor. For example, it may not restrict the program from being used in a business, or from being used for genetic research.

7. Distribution of License

The rights attached to the program must apply to all to whom the program is redistributed without the need for execution of an additional license by those parties.

8. License Must Not Be Specific to a Product

The rights attached to the program must not depend on the program's being part of a particular software distribution. If the program is extracted from that distribution and used or distributed within the terms of the program's license, all parties to whom the program is redistributed should have the same rights as those that are granted in conjunction with the original software distribution.

9. License Must Not Restrict Other Software

The license must not place restrictions on other software that is distributed along with the licensed software. For example, the license must not insist that all other programs distributed on the same medium must be open-source software.

10. License Must Be Technology-Neutral

No provision of the license may be predicated on any individual technology or style of interface.

examples of proprietary software projects and development models.

The documented failure of the industrial model of software development is almost as old as the software industry itself. IBM's OS 360 project, begun in 1961, was perhaps the most ambitious attempt to industrialize the development of software.^[17] Fred Brooks, the IBM executive responsible for the project,^[21] hired the best coders, managers, analysts—whatever it took. And IBM ended up spending more money to produce that operating system than the U.S. Government spent on the Manhattan Project to develop the first atomic weapon, a fact that greatly troubled IBM's CEO at the time, Thomas Watson Jr. The product shipped—barely—in 1965, and though the product was a great commercial success, IBM's CEO really wanted to understand how it was possible that the software part of the project was so much more difficult and costly

than the hardware part. He put the question to Brooks, but Brooks himself did not have a ready answer. Ten years later Brooks answered the question in the form of a book titled *The Mythical Man Month*. The title comes from his insight that "it takes a woman nine months to have a child, no matter how many women are assigned the task." This was the first clue that the process of industrialization—breaking down tasks into simpler steps, optimizing the steps, and then managing the steps through production—had very significant limits when applied to software. Today, this book is often the first reference given to explain why multibillion dollar software projects like Microsoft's Vista slipped and slipped and slipped again, running wildly over budget and why, when it finally did ship, it did so without the very features that justified the project in the first place. Thus, more than 30 years later, we have the Gartner Group (who famously predicted the

success of the Personal Computer in enterprise computing) making the only logical prediction that can be inferred from *The Mythical Man Month* and Microsoft's own experience.^[22]

Vista will be the last major release of Windows in its current form. The current, integrated architecture of Microsoft Windows is unsustainable—for enterprises and for Microsoft. Each new version integrates more functionality and features, adding to the scale and complexity of the operating system.

While IBM and others struggled to industrialize software, the mainstream industrial model itself was beginning to show weakness across the board. In the 1940s, Dr. W. Edward Deming properly identified serious problems with the model that focused on optimization in terms of measurable (but arbitrary) inputs and outputs as related to costs and production. Deming had no luck convincing American companies to focus on quality as defined by the customer, nor to recognize the value of people working in teams on a larger and transforming goal, nor to consider whether work gave people joy. However, Deming did find a receptive audience in Japan, and the transformation that resulted from his approach has set the standard for modern industry, lowering costs, accelerating innovation, reducing environmental impact, improving safety, and inspiring pride in workmanship.^[23]

By the 1980s, Deming's work had reached even those still trying to industrialize software, in the context of the Software Engineering Institute (SEI) and their Capability Maturity Model (CMM) in a 1987 SEI Technical Report.^[24] First adopted not in the United States, but offshore, in Chennai, India,^[25] it was credited with dropping software defect density 98% while doubling profits. Though these first attempts have now been retired,^[26] the urgent question remains: why is software quality so low?^[27]

In 2005, Bill Gates gave a keynote speech at the RSA Security conference where he said "We spend over US\$6 billion a year on research and development. I'd say that over a third of that is directly security-focused, and the other two-thirds all tie in and relate to that security work, all the new code being reviewed and going through the threat model, a pretty dramatic thing there."^[28] Why is it that companies like Microsoft spend fully a third of their R&D budget correcting remedial security problems that should never have existed in the first place? As President of the OSI and Vice President of Open Source Affairs for Red Hat, I believe software quality is low because companies place a higher value on control than on innovation or quality or transparency or user participation. It is a failure to understand both the negative lessons that Brooks have taught, as well as the positive lessons that Deming taught. And perhaps it is because those who have achieved great status, wealth, and power are rarely willing to trade all

three for a new system that requires accepting new, disruptive assumptions.

The most significant transformation in ICT has been the emergence of Free and Open Source Software (FOSS).

Consider the popular Internet as embodied by the World Wide Web. This vision was first published by Vannevar Bush in 1945,^[29] and prior to 1990 there had been dozens of attempts to create such systems, the most popular being the French MiniTel system.^[30] But none of these systems became truly ubiquitous until the underlying software was free as in freedom. The freedom to read, modify, and share Web server and client code led to an explosion of innovation, and to date the most popular product of that explosion, the Apache Web server, remains dominant in spite of considerable efforts by some powerful companies to take over that space.^[31]

This came as no surprise to Tim Berners-Lee, creator of the World Wide Web, who explained his decision to make the original Web software free and open:^[32]

[H]ad the technology been proprietary, and in my total control, it would probably not have taken off. The decision to make the Web an open system was necessary for it to be universal. You can't propose that something be a universal space and at the same time keep control of it.

The popular Internet has created a dramatic new factor in the software industry equation, which is that developers and users represent a creative continuum, not distinct castes. Developers can be any people interested in a problem, not merely people employed to work on a specific problem. Free and Open Source software turns on its head the practice of optimizing software production by limiting the number of people working on a problem. Instead, those employed (producers), those annoyed (customers), and those who merely enjoy working on a problem (hackers)^[33] can work together in a problem-specific, rather than organization-specific or property-specific way. In his book *Democratizing Innovation*, Eric Von Hippel presents several studies which, together, show that 85% of all quantum innovation (as opposed to incremental innovation) is user-driven.^[34] The proprietary software model therefore limits innovation to one-sixth of its theoretical potential.

The democratization of innovation has also demonstrated a remarkable solution to the problem of *The Mythical Man Month*, thereby transcending the limits of conventional industrialization. For example, *sourceforge.net* is an open source development resource that hosts over 180,000 projects and has more than 1.9M registered users as of December 2008.^[35] Extrapolating from the extensive Free, Libre, and Open Source Software (FLOSS) survey of 2002^[36] (and updated in 2005)^[37] there were over 490,000 *sourceforge.net* developers in 2006 (when the thesis of this section was first developed—Tiemann) who spend more than 10 hr a week or more tending their open source

projects^[38]—an aggregate effort of some 5 million person-hours per week. The three top reasons they list for their involvement is:

1. Because it's fun.
2. Because it improves their skills.
3. Because it is good for society.

Note that this does not include Linux developers (who use *kernel.org*, not *sourceforge.net*), nor Apache, nor the GNU project, nor many of the other larger and more heavily commercialized open source projects. To put these 5 million joy-filled person-hours per week into perspective (again, this does not include Linux, Apache, GNU, or many of the other “large” projects), let's look at the productivity potential of the most successful proprietary software company, Microsoft, in two ways (using numbers that were contemporaneous with the FLOSS survey data, October 2006):

1. If all 61,000 employees^[39] wrote code, they would have to work over 80 hours per week.
2. If Microsoft's \$6.6B per year R&D budget^[40] were spent on programmers averaging just \$25 per hour, they could pay for about 5 million person-hours of work per week.

Thus, the *sourceforge.net* Web site has equaled or exceeded Microsoft's productive potential using a social, not an industrial model. When we consider all the open source developers not included in the *sourceforge.net* numbers (numbers that are increasing exponentially), we see the clear emergence of a new software production capacity entirely outside the conventional limits of the industrial model. Moreover, we find precisely the kind of improvements that Deming would have predicted by taking a transformative approach: according to findings published by Coverity (references below), typical proprietary software has a defect density of 20–30 defects per 1000 lines of code (KLOC), a number relatively unchanged since the 1960s. When they measured the quality of the Linux kernel (and later, other open source software) they found the following results:

- 2004: 985 defects in 5.7 MLOC of Linux kernel source code, or 99.3% lower defect density than average (compared to 114,000–171,000 defects in the same amount of code).^[41]
- 2005: While the Linux kernel grew 4.7% in overall code size, defect density decreased by 2.2%. Moreover, 100% of all “serious” defects identified were fixed within 6 months.^[42]
- 2006: The survey was expanded to entire LAMP stack and an additional 32 OSS programs. No correlation found between size and defect density, implying OSS

development methodology is not limited by scale (nor restricted to just Linux developers).^[43]

What the top industrialists could not achieve with proprietary software and financial capital, free software has demonstrated with community development and intellectual capital.

But free and open source has done more than revolutionize the production or the quality of software. The open source model has opened innovation. Open source helped crack grand challenge science problems such as sequencing the human genome.^[44] The world's largest public search engine, google.com, is built on open source.^[45–47] Open source has become a fixture in tech-heavy disciplines such as financial services,^[48] military intelligence,^[49] online retailing,^[50] and next-generation cellular telephones and base stations^[51] and handsets, including the recently announced Google Android project/product.^[52] And open source is helping to bridge the digital divide for millions of children who are literally off the grid.^[53] The model has even informed the strategy of the Bill & Melinda Gates Foundation to better combat infectious diseases:^[54]

[On July 20, 2006] the Bill & Melinda Gates Foundation announced that it would require that any researcher who accepts its grant monies for HIV/AIDS research will have to agree to share their scientific findings. The Gates Foundation was apparently frustrated that two decades of secrecy and competition among AIDS researchers have impeded efforts to come up with an AIDS vaccine.

Clearly there is a bright future for those who embrace the open source model, whether as users, developers, or entrepreneurs. The best way to learn more about open source is to become involved in a project, first as a user, then as a person who reports bugs or tests releases, and then follow where interests or expertise leads. Different projects have different personalities and protocols, but almost all viable projects have a history of being inviting at some level, and almost all provide concrete rewards for participants of all kinds. And with open source software doubling in size and scope every 12.5 months,^[3] there are more than enough examples to demonstrate why open source has become an increasingly preferred method of software development, procurement, and deployment, as the above references make clear.

Oral History in Libraries and Archives

Debra Gold Hansen

School of Library and Information Science, San Jose State University, Yorba Linda, California, U.S.A.

Abstract

This entry reviews the development of oral history in the United States, covering its theory and method, major professional associations, and influential programs. It also describes how oral history collections are processed, cataloged, and made available for public use and concludes with a discussion of the international oral history movement.

INTRODUCTION

Oral history is an historical/archival method of recording the memories of individuals involved in a specific historical event or era. The term oral history encompasses both the creation of the interview as documentation in historical study and the processing and preservation of the recording in a library or archives. These historical/archival activities can occur together as a holistic project. In other instances, the interview is conducted solely for research purposes and afterwards it is deposited in an historical repository. Regardless of the interviews' origin or purpose, oral histories exhibit key characteristics which distinguish them from other forms of oral documentation such as folklore and oral tradition.

This entry will survey the origin and progress of the oral history movement, its theory and method, and the major functions of its professional infrastructure. It will also note the major oral history programs in the United States and trace how oral history collections and their administration have evolved since the 1950s. The entry covers recent theoretical trends and concludes with the emergence of an international oral history movement.

ORAL HISTORY DEFINED

Defining oral history begins with what it is not. Although humankind has preserved its cultural memory for centuries, oral history differs from oral tradition in several ways. Oral tradition is passed down from generation to generation and does not require that the narrator be a participant in or witness to the event being told. Oral tradition also requires a narrator to memorize and perform the story as opposed to critically describing observed events. Neither is oral history an oral memoir, although an oral history interview includes elements of a life review. The difference here is that a memoir is an uninterrupted, unproblematic personal narrative. Oral history, in contrast, requires the

intervention of an interviewer, whose questions guide the narrator's reminiscences and probes for further reflection.

Oral history, then, is a structured conversation between a researcher and an individual who has witnessed or participated in a historic event. Its goal is to gather information that supplements and expands traditional primary source material such as personal papers and archival records. For some topics, oral history creates historical documentation where none other exists. Oral history is an audio form of historical evidence, though many oral history programs create verbatim transcripts for researchers' use.

HISTORY OF ORAL HISTORY

Although the present-day oral history movement originated following World War II, historians have made use of eye-witness accounts since ancient times. As early as the fifth century B.C.E. Herodotus used firsthand testimonies in his writing on the Persian Wars. There is evidence that personal narratives were recorded by scribes in China (1122–256 B.C.E.) and early modern Europe as well. Priests in colonial Latin America similarly preserved the stories of indigenous people, in this case to create a record of their declining civilizations.^[1]

In the United States, the term "oral history" reportedly was first used in 1863 when Joe Gould recorded overheard conversations in New York City for a book he never actually wrote called "An Oral History of Our Time."^[2] About this same time, historians and antiquarians began preserving pioneer reminiscences in more a systematic manner. A prolific collector was Lyman Copeland Draper. When he died in 1891, his interviews and papers collected from Revolutionary War veterans and other prominent individuals filled 486 volumes and were donated to the Wisconsin Historical Society.^[3] On the West Coast, historian/publisher Hubert H. Bancroft also recorded pioneer reminiscences, which he called "Dictations." The resulting 125

interviews with the state's leading Californios (i.e., pre-1848 inhabitants of Alta California) are now part of the University of California, Berkeley's Western Americana Collection.

Oral history fell into disfavor at the turn of the century as historians pursued what they believed to be a more objective means of understanding the past. Following the dictates of German historian, Leopold von Ranke, these so-called "scientific" historians preferred to ground their research in official written records and dismissed personal narratives as hearsay. However, as official and personal records gained ascendancy in historical writing, new forms of long-distance communication and modes of travel were causing them to disappear. The reel-to-reel tape recorder, invented in Germany in the 1930s, offered a solution by making it possible to permanently capture people's conversations.

The modern oral history movement began in the late 1940s, when Columbia University professor Allan Nevins employed several graduate students to interview important figures in New York politics and government. Nevins first raised concerns about the loss of primary sources in his 1938 book, *The Gateway to History*, proposing that historians make a "systematic attempt" to record the firsthand accounts of individuals important in contemporary society.^[4] In 1948, Nevins secured an endowment from the university's Bancroft Fund and the Columbia Oral History Research Office was born.

Columbia's oral history program set the agenda for oral history projects during the movement's formative period. The program was largely funded through grants and contracts, which reinforced its initial focus on prominent individuals in government and industry. (Among Columbia's early projects were oral histories of prominent government officials as well as executives of major corporations like the Carnegie Corporation, Ford Motor Company, Weyerhaeuser Timber Company, and McDonnell Douglas Aircraft.) Columbia's interviews were recorded in long-hand until the portable tape recorder became available in the early 1950s. Even after the interviews were recorded, they were still transcribed and the original tape destroyed or reused. Theoretically, early oral historians felt that the printed transcript—which included editorial corrections by the researcher and narrator—was the primary source of record, the tape being simply a conduit. Reusing tapes was also an economic measure, since the oral history method was expensive and funding scarce.

In 1958 Allan Nevins retired and turned over the administration of Columbia's program to his associate director, Louis Starr. Starr hired Elizabeth "Betty" Mason as his assistant, and together the two regularized and systematized the management of their growing oral history collection. They developed formal guidelines for conducting and processing interviews and arranged for formal deposit of the completed transcripts in the Special Collections Department at Columbia's Butler Library.

They also established policies regarding access to and use of the transcripts, which set in place various protections governing the interests and rights of narrators. In 1964, the Columbia Oral History Research Office published its first catalog containing descriptions of the program's 1345 interviews.

During the 1950s and 1960s, Columbia's Oral History Research Office continued to function as an independent, self-funded entity on campus. When it decided to offer a class in oral history, it did so not through the university's history department but instead in its library science program. According to Betty Mason, these original oral history classes attracted 16–20 faculty and students from various disciplines across campus. "We saw oral history as something which could be used in lots of different ways," she recalled. "Louis [Starr], in his speeches, used to talk about it being more than a tool and less than a discipline."^[5,6]

While Columbia University was developing oral history in the East, other programs were starting up in universities and government agencies throughout the country. In 1965, 89 different oral history centers were in operation; by 1971, 230 programs had begun with 90 more planned.^[7] Oral history programs were in colleges and universities, historical societies, private foundations, museums, and government agencies. Their collections ranged from interviews with Jewish labor activists to the lives of American composers.

Driven by technological advance and popular culture, oral history expanded rapidly in the 1970s. The inexpensive portable cassette player (invented in 1963) made oral history activity feasible outside government and the academy. Best-selling oral history-based books published by Studs Terkel and Alex Haley popularized the oral history method among the general public, and the oral history work of Eliot Wigginton's high school students with Appalachian old-timers attracted nationwide praise. By the time Haley's "Roots" aired as a wildly popular TV miniseries in 1977 oral history had come of age.^[8–10]

Key to oral history's development in the 1970s was a major theoretical shift from preserving the memories of prominent individuals to collecting the stories of everyday life. This new theoretical thrust was a by-product of changing lines of historical inquiry, most notably the emergence of the new social history. Often described as "history from below," social history documented the lives of nonelites—workers, women, and ethnic minorities—whose personal papers rarely found their way into the government archives or university library. It was an energizing time for oral historians, as Linda Shopes recalled. "I was excited by what I sensed to be oral history's potential for transforming that body of received wisdom called history, transforming it from the codifications of a few learned men to the experiences, attitudes, and perceptions of ordinary men and women."^[11] The major projects inaugurated at this time reflected oral history's widening

historiographical lens: Howard University's Civil Rights Documentation Project (now the Ralph J. Bunche Collection); Long Beach State University's Feminist Oral History Project; Radcliffe College's Black Women Oral History Project; Wayne State University's Autoworkers Oral History Project; and the Doris Duke American Indian Oral History Program to which many university's contributed interviews.^[12]

By the end of the 1970s, oral history had become an established historical methodology with a growing body of practical and theoretical literature. Much of the early writing on oral history appeared in library science and archival journals. In fact, between 1968 and 1978, more than 110 articles were published. Most reported on new oral history projects and collections. Some, however, raised concerns regarding the value of oral history as historical documentation and the role archivists should play in its creation and administration.^[13]

The 1970s saw the expansion of oral history books as well. Written by oral history pioneers, initially these texts focused on oral history methods. In 1969, Willa Baum, head of the University of California, Berkeley's Regional Oral History Office (ROHO), published one of the earliest manuals, *Oral History for the Local Historical Society*. A flurry of how-to guides appeared thereafter, including *A Guide for Oral History Programs* (1973), *Transcribing without Tears* (1976) and another text by ROHO's Baum, *Transcribing and Editing Oral History* (1977).^[14–17]

Coincident with the publication of these practical guides, oral history writing moved in a more theoretical direction. The turning point came in 1975 when Ronald Grele put together a small volume of essays titled *Envelopes of Sound*. With contributions from historians, anthropologists, and popular writers, *Envelopes of Sound* asked some challenging questions regarding oral history method and use. In the introduction, historian Alice Kessler Harris compared oral history to more traditional archival sources created as a natural by-product of daily activity. "Unlike diaries, letters, and personal papers that were themselves responses to the event or period being studied," Kessler Harris observed, "interviews are created after the fact and reflect the participants' self-conscious attempts to preserve what they remember for the future."^[18] In his essay "Movement without Aim," editor Grele also considered the authenticity of oral history as evidence, given the role played by the historian in its own creation. "The recorded conversations of oral history," Grele maintained, were "joint activities, organized and informed by the historical perspectives of both participants [narrator and interviewer]." They are not really autobiographies, he continued, but "conversational narratives." Their content must be understood within this unique framework.^[19]

Subsequent writings on oral history continued this introspection concerning the meaning and value of oral history as primary source material, especially in light of

criticisms coming from traditional documentary historians regarding the interviewees' faulty memories. David Henige, in *Oral Historiography* (1982), devoted several chapters to interpreting oral history evidence, stressing how the context of the interview's creation impacted the resulting content.^[20] Other publications confronted the issue of historical accuracy of interviews, suggesting ways in which information should be authenticated. There was also a growing interest in how other disciplines might use oral histories in their research. Publications such as Daniel Bertaux's *Biography and Society: The Life History Approach in the Social Sciences* (1981), David Dunaway and Willa Baum's *Oral History: An Interdisciplinary Anthology* (1984), and David Stricklin and Rebecca Sharpless's *The Past Meets the Present: Essays on Oral History* (1988), considered how interviews can serve as documentation for not just historical study, but also for sociology, cultural anthropology, literary studies, linguistics, and more.^[21]

This theoretical dialogue regarding oral history's creation and use came to full flower with Michael Frisch's 1990 book, *A Shared Authority: Essays on the Craft and Meaning of Oral and Public History*. A collection of his own ruminations of oral history theory and practice, Frisch explored how the interviewer, narrator, historian, and audience all play a part in constructing and interpreting the past. Frisch stressed that oral history is a socially constructed activity which not only reflects personal experience but also cultural forms and the context from which it emerges. An oral history interview, argued Frisch, is a mix of experience, memory, and cultural perspective. As such, it allows the researcher to "stand somewhat outside of cultural forms in order to observe their workings."^[22]

Questions about memory and oral history did not diminish its value as a primary source, but became its strength, allowing scholars to not only learn about what happened in the past, but also to see how memory can be influenced by culture and time. Moreover, the increasingly international exchange among oral historians (see below) has deepened practitioners' appreciation of the field's sociocultural implications and its multiplicity of uses. As British oral historian Alistair Thomson explains, the interview provides "clues not only about the meanings of historical experience, but also about the relationships between past and present, between memory and personal identity, and between individual and collective memory."^[23] Oral history has thus evolved from historians' desire to preserve the memories of powerful individuals into an important interdisciplinary tool for the study of society and culture.

ORAL HISTORY METHODS

Michael Frisch's concept of shared authority (that is, the redistribution of power between the historical actor and

the historian) has particular resonance for understanding the theoretical underpinnings of oral history practice.^[24] Typically oral history is not a single interview but a series of interviews to gain multiple perspectives on a given topic. The project director selects narrators based on their knowledge and representativeness of the community their story embodies. The interview itself is a dialogue between the interviewer, who has researched the topic extensively, and the narrator, who responds to a series of questions posed by the interviewer. While the interviewer prepares an outline of topics to cover, the narrator is encouraged to tell his or her story without interruption or contradiction. Oral historians typically ask open-ended, neutral questions. They listen patiently as the narrator reminisces at length or stops and pauses to consider his or her answer. Once the narrator fully responds to a given question, the interviewer probes for further details and reflection. The interviewer is expected to be sensitive to the narrator's perspective and personal background, allowing the interviewee to determine what will be discussed and how it will be expressed. This give-and-take between the interviewer and interviewee, and attentiveness to the narrator's feelings and values, allows for an oral historian to discover not only what happened but, in the narrator's view, why it happened and what it meant.

Once an interview has been recorded, a verbatim transcript is prepared and returned to the narrator. The narrator has the opportunity to review what was said in the interview and correct or clarify material not accurately expressed. The narrator can delete passages that, upon reflection, he or she would prefer to be kept off the record. When controversial material has historical significance, the interview might be sealed for a number of years or until vulnerable parties are deceased. The power of the narrator to review and approve the transcript before depositing it in a library or archives is a core component in this collaborative process and serves as the backbone of ethical oral history practice.

For both ethical and legal reasons, oral history transcripts are carefully vetted to prevent unintended harm to those mentioned in or connected to the interview. As the Oral History Association Evaluation Guidelines warn: "Interviewers should guard against possible exploitation of interviewees and be sensitive to the ways in which their interviews might be used."^[25] An oral history project will often employ editors to go through the transcript and identify material potentially injurious to the narrator, innocent parties, and the oral history program itself. Oral history programs can be held accountable for libelous or slanderous material contained in interviews subsequently published and distributed.^[26]

Because oral history methodology emphasizes the narrator's right to voice and control his or her own story, other protections are part of standard practice. In addition to reviewing and approving the transcript, the narrator signs a legal agreement form that deeds the interview to a

specific repository and outlines copyrights pertaining to its publication and future use. Before signing this release, the narrator is fully informed of his or her rights and told how the interview will be used. Because an oral history is a "coauthored" document, the interviewer signs a similar agreement form transferring his or her interest in the tape and transcript to the repository as well. Typically, a repository asks the narrator and the interviewer to transfer copyright to the institution so that the archives can control the interview's access and use. Without these signed release forms, an oral history collection cannot be made available to researchers and the public.

Although oral history methodology focuses on the recorded interview, the ultimate archival record includes collateral material in addition to the tape and transcript. In some programs, the interviewer prepares field notes about the interview experience that become part of the archival record. Oral history projects might accumulate other documentation, such as a narrator biographical form (to record personal and contact data about the interviewee), photographs, research files, and personal papers. Thus each interview in an oral history project generates a large body of documentary material in multiple formats. Once the project is completed, these materials are cataloged and shelved according to a system designed by the oral history program. Many oral history programs transfer completed projects to their institution's library or archives for curating.

CURATING ORAL HISTORY

Oral history curating refers to the administrative and archival activities surrounding the processing and management of oral history tapes and transcripts. It includes the paper trail that provides important context for researchers to understand the project's provenance and authenticity as a primary source. Curating also involves the management of legal rights as stipulated in the signed agreement forms. Finally, oral history curating requires the creation of various finding aids and access tools to promote oral history collection awareness and use.

For many years oral history curating was done by oral historians (as opposed to librarians and archivists) who focused on processing the interview. This included transcribing, editing, and indexing the recording. The standard text on oral history processing devoted a mere two paragraphs to the actual "curating" of a collection:

With the deposit of the interview(s) and related materials in an appropriate depository, the processing phase of oral history is completed. But the work is not done. If the interviews are to serve their intended purpose, they must be properly preserved, serviced, publicized, and used.

This passes over into the area of curatorship and involves such considerations as storage conditions for tapes, cataloging, publicity, dissemination of information about

holdings to appropriate regional and national information networks, and encouraging users. But that is a subject of another book.^[27]

As more and more historians conducted interviews in the course of their research, librarians and archivists had to consider oral history's place in an archives or manuscript repository. Some information professionals believed that oral histories were not true records, according to traditional definitions. Others pressed that archivists and curators collected documents created as a natural by-product of daily activity; to generate records themselves was both inauthentic and a conflict of interest. On a more pragmatic level, oral history collections—with their numerous interviews, legal forms, and multiple formats—did not fit into standard cataloging or other descriptive practices. Preserving reel-to-reel and cassette tapes, not to mention various generations of tape recorders to play them, presented problems as well.

On the other hand, historiographical developments in the 1970s and 1980s demanded that library and archival collections keep pace. Social history, in particular, called for new documentation strategies that would capture the histories of previously ignored groups and topics. Oral history provided an ideal opportunity for libraries and archives to expand their collecting areas and provide historical materials for an increasingly diverse clientele. In the 1980s, numerous articles appeared in the *Journal of Library History*, *American Archivist*, and other professional journals promoting the value of oral history collections. In 1983, the Society of American Archivists established its Oral History Section to coordinate and sustain the profession's growing interest in oral history materials.

A major obstacle in curating oral history collections was the dearth of cataloging models and standards. "In an age in which even artifact curators are moving toward a standardized format for information exchange," complained Bruce Bruemmer, archivist at the Charles Babbage Institute, "oral history remains steadfast in its reliance on the published guide."^[28] Indeed, since Columbia published its first oral history catalog in 1964, many programs printed their own collection guides. Other oral history centers created in-house databases of their interview holdings. Some simply kept an on-going list of narrators and topics. When librarians and archivists did catalog oral histories, they treated the transcript as if it were a book. This item-level approach to cataloging oral history was expensive and time consuming and discouraged many libraries from fully processing their recorded and transcribed interviews. As a result of these cataloging problems, curators and librarians frequently resorted to what might be called the shoe-box method: they put their oral history tapes in a shoe box and stowed them away on a remote shelf.

In the early 1990s, several prominent archivists, including Bruce Bruemmer, Lila Goff, James Fogerty, Stephen

Hearn, and Michael Fox, secured a grant from the National Historical Publications and Records Commission (NHPRC) to adapt standard cataloging rules for oral history collections. At the outset, they had to confront the uniqueness of the materials' origin and content:

The oral history interview has developed as a distinct intellectual form, sharing some characteristics of deliberately created works, such as monographs, and some characteristics of unself-conscious accumulations, such as archival records. Oral histories are sometimes both produced and managed by separate oral history program units within larger repositories (usually libraries or archives). Small repositories often acquire oral histories created by individuals, schools, or community projects which don't have the resources to undertake long-term preservation and management of their products.^[29]

The challenge, then, was to adapt descriptive cataloging rules and the MARC format to accommodate the full range of materials comprising an oral history collection.

The grant project was overseen by Marion Matters, who had previously worked on the Society of American Archivists' cataloging manual *Archives, Personal Papers, and Manuscripts* (1989). The resulting *Oral History Cataloging Manual*, published by the Society of American Archivists in 1995, was an important step in "mainstreaming" oral histories so that they could be included in online catalogs and bibliographic databases. Key was the decision to describe oral history as a collection or project. That is, oral history cataloging would take an archival rather than library materials approach so as to depict oral history as a group of materials related by provenance.

Another important step in oral history curating was the 1985 publication, *Oral History and the Law*. Written by history professor and municipal judge John Neuenschwander, this text provided authoritative discussion of laws, court cases, and legal precedents relating to the creation and use of oral histories. It provided sample legal forms and policy documents (i.e., release forms, deeds of gift, contracts, etc.) to guide curators in developing policies and procedures that met legal requirements. Successive editions have continued to keep oral historians informed of changing case law and how it affects oral history administration. (This guide is now in its third edition. See work by Neuenschwander).^[30]

A third element in curating oral histories involves tricky preservation issues relating to the sound recording. For many years, audiotapes were not preserved, despite pleas from several prominent archivists and librarians.^[31] (See, for example, speech by Louis Shores, Dean of Florida State University's School of Library and Information Science.) Ultimately changing oral history theory convinced oral historians of the recording's research value, so even when the tape is transcribed, it is now preserved as the primary source. As a consequence,

librarians and archivists must contend with the vulnerability of audiotape, its gradual degradation over time, the loss of quality when copied, and the obsolescence of machines needed for playback. Oral historians initially debated the merits of reel-to-reel vs. cassette tapes as the best format for archival preservation. The debate then shifted to the feasibility and potential impact of videotaped interviews. When digital recording became commonplace in the 1980s, oral historians argued over the positive and negative aspects of replacing more stable analog tapes with compact disks. As with earlier debates over preserving audio recordings, the analog vs. digital controversy has been decided by the marketplace. Now that reel-to-reel and cassette recorders have all but disappeared, oral history curators are engaged in large-scale digitization projects to preserve their analog collections on CD and in other digital formats.

Responding to growing concern about the long-term viability of sound recordings, the U.S. Congress passed the National Recording Preservation Act in 2000. This legislation authorized the Library of Congress to establish the National Recording Preservation Board (NRPB) to develop a comprehensive program to preserve America's recorded heritage. Comprised of sound experts from the music, library, and archival fields, the NRPB commissioned a series of publications on audio preservation and digitization. Of particular importance was the 2006 report, *Capturing Analog Sound for Digital Preservation*, which established best practices for transferring analog recordings to digital format.^[32]

Despite this progress in digitizing oral history collections, the transitory nature of digital technology makes long-term preservation increasingly elusive. As Kevin Bradley, curator of oral history and folklore at the National Library of Australia, observed in 2007, "The goal of a permanent media has been wrecked on the rocks of relentless progress. Even if any media could be claimed and trusted, as permanent, the quandary is that within a short period of time the storage system would be technically superseded by storage media exhibiting superior performance specifications, and manufacturers would no longer support the old technology."^[33] Currently sound preservationists speak of "digital sustainability" rather than archival permanence and argue that the storage, access, and migration of sound recordings must become part of a broader and continuing digital assets management program.^[34]

While posing troubling preservation issues, digitization has revolutionized how libraries and archives are making their oral history collections available to researchers and the general public. Initially, oral history programs prepared published directories containing brief annotations of the interviews in their collections. Once cataloging rules were developed, oral histories were added to large bibliographic utilities like OCLC and RLN as well as to more specialized primary source databases like Alexander Street Press's *Oral History Online*. Individual oral history

programs are now placing transcribed and recorded interviews on their institutional Web sites, expanding access to their collections in ways unimaginable when many of the interviews were originally conducted.

More recently, libraries and archives have begun developing new indexing systems to enhance access to digitized audio files. For example, the Shoah Foundation's Visual History Archives enables online searching of its 52,000 testimonies of Holocaust victims by indexing the interview in 1-minute time segments and linking the index terms to the original recording. The Virtual Oral/Aural History Archive at California State University, Long Beach, provides online access to 1000 hours of its interviews by connecting segments of the voice recording to written synopses of the interview's content. At the University of North Carolina, the Southern Oral History Program partnered with the University Library to develop an ambitious oral history database which contains both the transcript and the audio file so users can move back and forth between the text and spoken word. Perhaps most promising is the software currently under development by Randforce Associates that will embed indexing terms and cross references directly into the audio file, making the interview itself fully searchable.^[35]

These innovations in digital storage and access have profound implications for oral history methodology and practice. Digitization reemphasizes the aurality of oral documentation, allowing researchers to by-pass mediation imposed by transcribers, editors, and catalogers.^[35] At the same time, putting unprocessed, digitized oral histories on the World Wide Web raises new theoretical, ethical, and legal concerns which the oral history profession assuredly will address in the near future.

ORAL HISTORY ASSOCIATIONS

The diverse oral history community is tied together by a network of national and regional professional associations. Through conferences, workshops, discussion lists, and publications, these organizations foster standards and ethics in oral history practice and help disseminate information regarding new programs and projects.

The Oral History Association (OHA) had its genesis in the First National Colloquium on Oral History held in September 1966 in Lake Arrowhead, California. Spearheaded by University of California, Los Angeles, special collections librarian James Mink, the conference attracted over 70 participants, including the movement's founder, Allan Nevins. The historians, archivists, librarians, folklorists, psychiatrists, and medical doctors in attendance debated how to define oral history and what constituted good interviewing technique. They also considered ethical issues involving funding arrangements and interview use. Conference organizer Jim Mink recalled that the "hottest and heaviest" topics were "keeping the tapes" and the editing the transcripts.^[36]

It was not at this meeting, but at the second national oral history colloquium that the Oral History Association was officially established. Held in New York City in November 1967, the 145 oral historians present chose Columbia's Louis Starr as OHA's first president and crafted the organization's constitution. One of OHA's earliest priorities was to establish connections with library and archival groups to promote oral history as a documentary source. Oral History Association representatives spoke at American Library Association, Society of American Archivists, and other professional conferences and contributed articles about oral history to their publications.^[37]

The OHA continued to host annual fall conferences, attracting a multidisciplinary audience interested in the conduct and use of oral history. From 1966 through 1972, the association recorded and transcribed conference proceedings and distributed them among its members. As the field matured, the OHA sought to expand its publication's coverage, and in 1973 began its journal, the *Oral History Review*. Under the founding editorship of Samuel Hand, the *Review* came out once a year. It continued to publish selected conference presentations and OHA board meeting minutes, but featured articles by leading oral history theorists and practitioners, and, after 1976, added book reviews. The publication of meeting minutes was dropped in 1981, making the journal a purely refereed periodical. The *Oral History Review* is now published twice a year, affiliated with a prominent university press, and continues as major source of professional and theoretical discourse for the field.

In addition to hosting conferences and publishing the *Oral History Review*, the OHA sponsors a helpful pamphlet series and other publications to codify and promote professional practice. The quarterly *Oral History Association Newsletter*, edited for many years by Baylor University historian Thomas Charlton, provides a window on current oral history issues and events. The pamphlet series addresses topics of general concern, such as "Using Oral History in Community Oral History Projects" and "Oral History Projects in Your Classroom."

The OHA also maintains an influential and highly regarded policy document called "Oral History Evaluation Guidelines." Available on the OHA Web site and reprinted in every oral history text, these guidelines were developed at the 1979 "Wingspread Conference" to define and describe ideals of oral history practice. (The Wingspread Conference was named after the conference center in Racine, Wisconsin, where the meeting was held.) Revised in 1989 and again in 2000, the current version sets forth oral historians' ethical and professional responsibilities to the interviewees, the public, the profession, and the sponsoring institution. In addition to establishing standards for oral history conduct, the Evaluation Guidelines also include best practices for oral history project design and implementation. Taken together, these guidelines and standards serve as a benchmark against which oral history work can be assessed.^[38]

The oral history movement is also supported and sustained by a network of regional associations. These local groups are quite active, holding annual conferences, organizing workshops, and publishing newsletters. They also raise money for scholarships and give awards for significant oral history work in their regions. Presently there are seven active groups: Michigan Oral History Association, New England Association for Oral History, Northwest Oral History Association, OHMAR—Oral History Mid-Atlantic Region, Southwest Oral History Association, and Texas Oral History Association.

MAJOR ORAL HISTORY PROGRAMS

"Let us begin by disposing of the myth that I had anything to do with the founding of oral history," protested Allan Nevins at the first national meeting of oral historians in 1966. "It founded itself," he asserted, and "would have sprung into life in a dozen places, under any circumstances."^[39] Although Columbia's Oral History Research Office is credited with launching the modern oral history movement in the United States, Nevins rightly recognized that other historians were beginning to record interviews about the same time.

Several government-funded projects predate Columbia's pioneering work. The Federal Writers' Project, a New Deal program sponsored by the Works Progress Administration between 1935 and 1943, employed over 6600 interviewers to collect the stories of Americans representing all walks of life. (These interviews are now available online through the Library of Congress's American Memory Historical Collections.) During World War II, the United States Army hired historians to accompany troops into battle and record their experiences as they were happening. The Army continued its oral history program after the war, and today over 1200 interviews with military men and women are available at the U.S. Army Center of Military History.

The U.S. Army is not the only government department to employ oral history. Since the 1960s all branches of the armed forces have sponsored oral history projects to supplement their documentary record.^[40] One of the largest collections is housed at the Marine Corps Historical Center and includes interviews with nearly 6500 soldiers who served in Vietnam. The U.S. Senate Office also has an important oral history program dating back to 1976. Under the direction of Senate historian Donald Ritchie, hundreds of interviews have been conducted with senators and people associated with the Senate spanning half a century.

American presidential libraries were another significant player in the American oral history movement. The Roosevelt Presidential Library was the first to collect oral histories, contracting with the Columbia Oral History Office to interview individuals associated with Roosevelt's administration. The Truman, Hoover, Eisenhower, Kennedy, and Johnson presidential libraries also sponsored major oral

history projects in the 1960s and 1970s, often hiring full-time oral historians to oversee the work. The Johnson Presidential Library, which interviewed people while Johnson was still in office, boasts the largest oral history collection, with over 1500 interviews in its archives. Presidential libraries established since the Carter Administration have not undertaken such large-scale oral history projects, but instead preserve exit interviews done with White House staff members leaving office.^[41,42]

Other federal agencies and institutions have also used oral history to document their programs and activities. The National Institutes of Health, National Library of Medicine, Social Security Administration, NASA, and the National Parks Service have all conducted interviews since the late 1960s. Today the Smithsonian Institution has an ambitious oral history program dealing with the history of aeronautics, science, and technology. The Smithsonian also sponsors important oral history projects for the Archives of American Art and on the history of American jazz.

The most impressive government-funded oral history work is happening at the Library of Congress. Its American Memory Web site contains thousands of interviews recorded by federal employees or donated by the general public. The Library of Congress also sponsors the Veterans History Project which asks former military personnel to donate oral histories and documents relating to their wartime experiences. At this writing, the Veterans History Project contains more than 45,000 personal testimonies, making it one of the largest oral history collections in the world.

Much of the oral history activity in the United States takes place in colleges and universities. As more and more faculty used oral history in their research and teaching, they needed an institutional base to manage the expanding body of documentary materials, leading to the establishment of oral history programs on campus. California's universities provide a good case in point. In the early 1950s, James Hart and George Stewart, English professors at the University of California, Berkeley, were inspired by Bancroft's "Dictations" to hire graduate students to interview additional California pioneers. In 1954, the university established the Regional Oral History Office to coordinate this oral history effort. The University of California, Los Angeles, began its oral history program in 1959, the brainchild of British historian John S. Galbraith and University Librarian Lawrence Clark Powell. The University of California, Los Angeles (UCLA) oral history program was initially managed by faculty member Doyce Nunis and librarian Elizabeth Dixon, until Special Collections Librarian James Mink, who as a graduate student had earlier worked on the Berkeley oral histories, assumed responsibility in 1967. Claremont College's Oral History Program was founded in 1962 by history faculty members Douglass Adair and W. John Niven. Niven had been a student of Allan Nevins at Columbia University,

and Nevins served as a consultant to Claremont's program in its founding years. Forty miles away, California State University, Fullerton, history faculty were also conducting interviews for their research and assigning oral history projects in their classes. The Cal State Fullerton oral history program was founded in 1968 by Gary Shumway and administered jointly by the history department and the university library.^[43-45]

California has been a hotbed of oral history activity for over 40 years, which explains why the first national oral history meeting was held in that state. However, many other regional colleges and universities are equally productive and influential in the field. It is not possible to list every major academic program, but any count would have to include: the Oral History Institute at Baylor University; the Southern Oral History Program at the University of North Carolina, Chapel Hill; the Maine Folklife Center at the University of Maine, Orono; the Center for the Study of History and Memory at Indiana University; the Center for Oral History at the University of Connecticut, Storrs; the Oral History Program at the University of Alaska, Fairbanks; the University of Kentucky Oral History Program; and the University of Nevada, Reno Oral History Program. These programs are significant not only for their collections, but also for the leading role they take in conducting oral history institutes, publishing oral history manuals and texts, and making available other oral history products and services.

Although government and university-based projects dominate the American oral history movement, public libraries, historical societies, and museums have also successfully used oral history to enhance their historical projects, exhibits, and collections. The New York Public Library (NYPL), for instance, began its Oral History Project and Archive in 1974 to document the history of dance. A significant project within NYPL's dance archive are interviews with dancers afflicted with AIDS. Smaller libraries have also relied on oral history to document their distinctive communities. A good example is the "Front Porch Oral History Series" sponsored by the Way Public Library, in Perrysburg, Ohio, which videotapes and preserves conversations with longtime residents born before 1930.^[46,47]

Oral history is also an important tool for preserving institutional memory, in both the for-profit and nonprofit sectors. The Forest History Society was, perhaps, the first organization to use oral history to document changes in its field of interest—forestry management and conservation—beginning its oral history collecting in the late 1940s. Many other organizations have followed suit and developed important oral history projects to document the experiences of individuals in their organizations and communities. Among the most ambitious is the Shoah Visual History Foundation, founded by film director Steven Spielberg in 1994 to videotape the stories of holocaust survivors and witnesses. Nearly 52,000 interviews

have been collected as a result of this project. They are now part of the Shoah Foundation Institute, established at the University of Southern California in 2006.^[48]

INTERNATIONAL ORAL HISTORY MOVEMENT

Although oral historians have been active outside of the United States for 60 years, the oral history movement has been self-consciously international since the 1980s. The first International Conference on Oral History was held in England in 1979; the *International Review of Oral History* began publication the following year. Renamed the *International Annual of Oral History* in 1990, it merged with the European oral history journal *Life Stories* in 1992 to become the *International Yearbook of Oral History and Life Stories*. Interdisciplinary as well as international, each *Yearbook* addressed a different theme, such as memory and totalitarianism, cultural transmission between generations, and migration and identity. The *Yearbook* ceased publication in 1996 when the International Oral History Association was established. In addition to sponsoring biennial conferences, the association publishes the bilingual, *Words and Silences/Palabras y Silencias*, continuing the *Yearbook's* mission to promote dialog among oral historians throughout the world.

Oral history's internationalism has challenged accepted oral history methodologies and fostered new theoretical understanding and applications. For example, oral historians' experiences interviewing people in different cultures have better illuminated the extent to which memory, culture, and the telling of history are interconnected and grounded in social context. Interviewing techniques promulgated in one region or culture may be entirely inappropriate and counterproductive in another.

The international movement in oral history also shows that the motives behind and uses of oral history vary in different parts of the world. While in the United States oral history originally sought to document the experiences of political leaders, the oral history movement in England, led by sociology professor Paul Thompson, has focused more on nonelites as a means of empowering the lower classes. Oral history in Latin America has an openly political agenda and is tied to important social movements of the region. Oral historians in postapartheid South Africa have found in oral history a means to cultivate a new national identity that, to quote its Oral History Association, "encompasses all people, irrespective of race, culture, genders, sexual orientation and social status."^[49] In New Zealand and Australia, capturing the history of aboriginal peoples has been among those regions' major oral history goals.

Finally, some of the most significant theoretical developments in oral history originated within this international setting, particularly in the work of Luisa Passerini and Alessandro Portelli. Passerini, in her studies of Italian

women and the working class, uses sociological, psychological, and feminist theory to better understand the multiple "subjectivities" of oral history interviewees and the fluidity of their personal narratives depending on the interview's context and goals. [See, for example, *Fascism in Popular Memory: The Cultural Experience of the Turin Working Class* (1987) and *Memory and Utopia: The Primacy of Inter-Subjectivity* (2007).] Portelli, arguably the most influential contemporary oral history theoretician, writes about how communities create and popularize their own historical narratives, sometimes in opposition to what actually transpired. As Portelli explains in *What Makes Oral History Different?* oral history "tells us less about events than about their meaning." [As cited in work edited by Perks and Thomson.^[50] Portelli's books include *The Order Has Been Carried Out: History, Memory, and Meaning of a Nazi Massacre in Rome* (2003); *The Battle of Valle Giulia: Oral History and the Art of Dialogue* (1997); and *The Death of Luigi Trastulli and Other Stories: Form and Meaning in Oral History* (1991).]

CONCLUSION

In this encyclopedia's original essay, Louis Starr defined oral history as "primary source material obtained by recording the spoken words—generally by means of planned, tape-recorded interviews—of persons deemed to harbor hitherto unavailable information worth preserving." These interviews, Starr elaborated, were not solely conducted for researchers' personal use, "but for libraries or other repositories to hold for the benefit of scholars of this and succeeding generations." Reflecting the status of oral history in 1977, Starr's entry focused on the strengths and weaknesses of oral history as historical documentation and chronicled the growing list of publications based on oral history interviews. Starr could already see social history's impact on oral history, noting that this historical methodology had the potential to "reflect the myriad interests of a pluralistic society." Starr was also enthusiastic about emerging technologies, most notably microforms, and their promise to extend oral history's reach beyond the originating institutions. Despite oral history's success and future prospects, Starr still bemoaned the fact that many historians continued to reject oral history as primary source material. He also criticized archival and educational institutions for not providing the financial support oral history programs sorely needed.^[51] (See also work by Fogerty^[52] for a similar comparison between Starr's early writings and contemporary oral history.)

While the spirit and substance of Starr's oral history remains much the same, there are important changes as well. Whereas Starr claimed that the vast majority of oral history producers and users preferred the typed transcript, today's interdisciplinary and theoretically attuned

researchers rely as much on the audio as the printed document to do their work. Starr was impressed with the many books using oral histories in the 1970s. Today's important publications are as much about oral history as based upon its interviews. And while Starr complimented oral historians on their printed catalogs and openness to new technologies, contemporary curators look to digitization to make oral histories available to researchers and the public. The opportunities of the World Wide Web, unimagined in Starr's time, have raised new issues concerning narrator rights. So while Starr barely mentioned legal and ethical practice in 1977, today they are central to oral history curating.

Starr concluded his essay rather plaintively, stating that until more universities and research libraries "perceive the work as central to their purpose" the full impact of oral history would not be felt.^[53] Today oral history enjoys wide acceptance, its value as both historical and cultural documentation is fully appreciated. Librarians and archivists are integrating oral history holdings into online catalogs and databases and developing exciting new ways of disseminating digitized tapes and transcripts on the World Wide Web. It appears that the days of shoe-box cataloging are coming to an end as oral history finds its rightful place in library and archival collections.

ORCID

Laurel L. Haak

Open Researcher and Contributor ID, Inc. (ORCID), U.S.A.

Abstract

ORCID is a nonprofit organization dedicated to providing an open registry of unique person identifiers for researchers, and to working collaboratively with the research community to embed these identifiers in research workflows to connect researchers and research. Together, the registry and embedding of identifiers supports discoverability and ensures that researchers get credit for their work. This entry describes the ORCID mission and organizational structure, describes relationships with other identifier systems, and provides details on the use of technical tools to support adoption and embedding of ORCID identifiers in research systems.

ORCID (<https://orcid.org>) was founded in 2010, a product of conversations among commercial and association publishers, research funders, universities, repositories, researchers, and data providers, who together determined that to solve the name ambiguity problem in scholarly and research communication required an organization that represented the entire research community without proprietary interest. ORCID spans sectors, disciplines, organizations, and nations. It is a community-driven effort to implement a standard and persistent representation of an individual contributor's name, and to link that standard to others, such as document and dataset identifiers, research sample identifiers, grant identifiers, association membership, other person identifiers, and other research activities as determined by the community. Together these linkages support the unique identification of an individual connected with their research contributions.

WHAT IS AN ORCID ID?

The ORCID identifier is a 16-digit number, expressed as a URI, that is unique to an individual. The format of the ORCID iD is consistent with the ISNI ISO 277729 standard, and ISNI has set aside a block of numbers from its range for assignment through the ORCID registry. An example of an ORCID iD is <https://0000-0001-5109-3700>. Display guidelines are posted online at <http://orcid.org/trademark-and-id-display-guidelines>.

WHAT DISTINGUISHES ORCID FROM OTHER IDENTIFIERS FOR RESEARCHERS?

ORCID is different in three ways. First, ORCID is an open effort. ORCID code and APIs are available as open-source code (see <https://orcid.org/blog/2013/02/21/orcid->

<https://orcid.org/blog/2013/04/22/orcid-and-isni-issue-joint-statement-interoperation-april-2013>). Second, ORCID links to other identifiers, making it possible for researchers to connect their work between existing systems, whether they are disciplinary or organizational, without devaluing those systems. The ORCID registry supports identifier linkages and metadata exchange with many identifier systems including Scopus Author ID, Researcher ID, and ISNI. ORCID and ISNI are committed to interoperation (see <https://orcid.org/blog/2013/04/22/orcid-and-isni-issue-joint-statement-interoperation-april-2013>). Third, ORCID is a community-wide effort. It does not stop at providing a registry, but also works to ensure the identifier becomes part of the metadata on works and research activities at the time the work enters the public domain. This removes author ambiguity for new works and makes it possible to use metadata to link back with an individual's ORCID record and automate the update process. Together, ORCID makes a researcher's work more easily discoverable, regardless of the system used to search. In short, the goal of ORCID is interoperability through community collaboration.

THE ORCID REGISTRY

The ORCID registry is a hub for linking information between systems and sources. As such, to the extent possible, ORCID uses persistent identifiers, such as DOIs for publications and datasets, to establish a persistent connection between the ORCID record and the object. We capture metadata in addition to the object identifier but do not capture or store objects themselves.

The registry is researcher-driven. Located at <https://orcid.org>, an individual may register and obtain an identifier without fee or membership requirement, nor are there requirements to qualify as a researcher. To register,

an individual must provide their name, e-mail address, create a password, and accept the ORCID privacy policy and terms of use. ORCID does not collect date of birth, financial, or government identification information. A user may augment their ORCID identifier by adding additional information such as other names they have published under (e.g., their married name or name expressed in different character sets), research area keywords, website URL, other e-mail addresses, and country in which they are currently employed. A user may also add information on their organizational affiliations, and search external databases through the ORCID registry to link their record to their existing research works, such as publications and datasets, and in some cases, push their ORCID identifier into these databases.

The ORCID iD is always public and may never be deleted. Individual users control the privacy of all other information in their record. A user may set each data field to either public, limited access, or private. Public data are searchable and viewable by anyone and are provided by ORCID to the public in an annual data snapshot under a CC0 waiver. This waiver means that ORCID makes no copyright, related, or neighboring rights claims to the aggregated data. Limited access data are only available for search or view by ORCID members that the user has specifically approved. Private data is only viewable by the user or their designated proxy.

Through adoption and embedding, ORCID is becoming a part of the metadata for publications and other works, making it possible to automatically update ORCID records with new research works metadata. ORCID iDs are being embedded in publisher workflows, grant application and reporting systems, university research information and personnel systems, repository submission systems, dataset management systems, and professional society member and meeting management systems. Each of these workflows supports a validated linkage between a researcher and their works.

COMMUNITY INVOLVEMENT AND GOVERNANCE

ORCID is governed by an elected board of directors, majority nonprofit, comprised of 11–15 members of the global scholarly research community <https://orcid.org/about/team>. Membership in the board of directors is drawn from and representative of ORCID member organizations. The board is responsible for establishing general policies for the governance of ORCID based on a set of core principles, among them openness and transparency. In addition to the board of directors, ORCID has several steering and working groups, open to the research community.

The ORCID community includes individual researchers, universities, national laboratories, commercial research organizations, research funders, publishers,

national science agencies, data repositories, and international professional societies, all of whom have been critically affected by the lack of a central registry for researchers. Prior to the launch of ORCID, over 300 organizations had registered their support for ORCID, and 50 of these provided start-up financial support. Since launch, a number and variety of organizations are integrating ORCID identifiers into their research workflows, using the application programming interfaces (APIs) ORCID has made available. A list of ORCID members, sponsors, and partners is available on our community page, at <https://orcid.org/about/community>.

ORCID has established groups to guide and support the evolution and ongoing development of the ORCID system. These are structured to facilitate broad and open participation of interested community members, provide opportunities to participate with different levels of time commitment according to interest and expertise, and provide ORCID guidance on priorities and execution of specific plans. ORCID encourages and welcomes community involvement in our business, outreach, and technical activities, ad hoc working groups, and community groups.

Our principles of openness and transparency extend into how the registry is managed. Development is carried out with new features and bug fixes tracked in an open manner. In addition, ORCID has implemented tools for community technical input, both through an open code repository and a support forum, where users are encouraged to submit ideas for new features, and view and vote on existing submissions. Input from both channels feeds into the prioritization of development work.

ORCID staff include the executive director, technical and outreach directors, and internal and contract technical staff. ORCID maintains a distributed office, with a primary location in Bethesda, MD. ORCID Inc. maintains a governance relationship with its ORCID EU affiliate but is distinct from a financial and legal perspective.

DATA PRIVACY AND SECURITY

Confidence and trust are important to ORCID. We have put in place controls, policies, and practices (see <https://orcid.org/about/trust>) so that connections are controlled by researchers, and that the source of each connection is openly articulated.

Researcher privacy is important to ORCID. Following research community-sanctioned privacy practices is essential to the success of ORCID and the registry it operates. ORCID is committed to providing users with meaningful choices about privacy and the ability to control how information is used. The ORCID privacy policy is available online at <http://about.orcid.org/privacy-policy>.

A core ORCID principle is that users control the privacy settings of their own ORCID record data through

various opt-in features. To that end, ORCID allows users the right to control how their information is published on and shared via the ORCID registry. Data marked as *public* is available to the public for viewing and use, including commercial use. Data marked as *limited access* may be viewed through the registry by the user, their designated proxy (if any), or the user may elect to share a field or specific data within a field with trusted parties. Data marked as *private* are viewable only by the user or their designated proxy.

To ensure the transparency of the registry, ORCID maintains an audit trail of when and by whom registry information has been deposited or changed and any changes to privacy settings. ORCID uses this information to assist users in addressing concerns about the provenance of data in the registry and questions about identity ambiguity or theft. ORCID reviews concerns about data in accordance our dispute resolution procedure (see <http://about.orcid.org/content/orcid-dispute-procedures>), which includes the provision to remove or hide from the registry and its servers any record data that violates the privacy, publicity, or other rights of any person.

ORCID is committed to protecting the registry and users from unauthorized access to or authorized alteration, disclosure, or destruction of personal information in the ORCID registry or which we otherwise hold. ORCID stores information in a data center with restricted access and uses a variety of technical security measures to secure data. We also use secure socket layer (SSL technology) and intrusion detection and virus protection software. Data are stored on servers that are not accessible directly via the Internet. We periodically review our information collection, storage, and processing practices, including physical security measures. We restrict access to information marked as private or limited access or which is otherwise not public. And, all passwords are hashed and are not visible to ORCID, its contractors, or agents.

ORCID may store and process personal information on servers or on a cloud located outside of the country where a user originally deposited the data. Regardless of where data are stored, ORCID takes steps to protect information, consistent with the principles set forth in the ORCID privacy policy, intended to comply with the Safe Harbor and Privacy Shield Principles issued by the U.S. Department of Commerce for data transfers from the European Union and Switzerland to the United States. As a not-for-profit organization, ORCID is not subject to the jurisdiction of the U.S. Federal Trade Commission, which oversees the implementation of Safe Harbor and Privacy Shield Principles. However, we adhere to the Principles in recognition of their importance in ensuring the protection of user information. We undergo an annual enterprise privacy certification review by an independent third party to verify our compliance with user data privacy management practices.

HOW IS ORCID SUPPORTED?

ORCID has many generous participants who have supported the start-up phase of ORCID: hundreds of volunteer hours from dozens of participants and board members, sponsorships and loans received from publishers; grants received from The Andrew W. Mellon Foundation, National Science Foundation, the European Commission, and the Alfred P. Sloan Foundation; the Leona M. and Harry B. Helmsley Charitable Trust, and a perpetual no-fee license of the Researcher ID code from Thomson Reuters.

Over the longer term, ORCID revenues are entirely derived from membership and subscriber fees from organizations that license the member API (see <https://orcid.org/about/membership>). In addition to a standard member and subscriber agreement, ORCID supports consortial membership and national membership. To support broad community adoption and use, ORCID provides fee-free access to a public API, including authentication and exchange of an ORCID identifier. Discounts are provided to nonprofit organizations, and to groups. Member policies are reevaluated regularly by the ORCID Board to ensure inclusiveness. Members and subscribers are listed on the ORCID website, at <https://orcid.org/about/community/members>.

EMBEDDING ORCID IDENTIFIERS

ORCID APIs

ORCID integration is entirely through APIs. There is no system to implement. As such, the technical work to embed ORCID identifiers into local systems involves mapping to the ORCID API. Maintenance involves monitoring the API documentation for updates and ensuring continued connectivity. ORCID APIs, software code, and documentation are posted in an open-source repository, and the community may obtain information on updates by registering for a mailing list.

ORCID provides two APIs. The public API, open for anyone to use, supports search of the public data in the registry. The member API is available only to those organizations that have accepted the terms of the ORCID member agreement. It supports authentication, search, read, write, and update. ORCID members may also serve as trusted parties, with the ability to read limited access data when approved by the user.

To support integration, ORCID provides a sandbox server for testing. Use of this server is free but requires registration and provision of a test token. It is the goal of ORCID, through provision of these tools and community resources to support not only integration of identifiers, but also the creation of tools and applications to interact with

the registry itself. Third-party tools already created include sites that use the APIs to consume ORCID works data and generate publication usage statistics.

Other APIs and Data Exchange Standards

Fields to capture ORCID identifiers are being added to other data exchange standards. The widely used CERIF standard for data exchange with research information systems (CRIS) includes a field to capture the ORCID identifier, as does the VIVO ontology, another CRIS system used in the United States, Australia, and Europe. The National Library of Medicine (NLM) article and journal DTDs both provide a field to capture ORCID identifiers as do several publisher production systems that submit article metadata to NLM and CrossRef. CrossRef captures ORCID identifiers during the journal article deposition process, and DataCite is doing the same for datasets. This information can be used to trigger a process to update the ORCID registry.

ORCID identifiers are included in the Journal Publishing Tag Library NISO JATS Version 1.0 XML specification. ORCID identifiers are captured in the `%contrib-id-type` attribute on `<contrib-id>` as the full URI. For more on the standard, see <https://orcid.org/blog/2013/03/22/orcid-how-more-specifying-orcid-ids-document-metadata>.

`<contrib-id>` Contributor Identifier

One identifier for a person such as a contributor or principal investigator. This element will hold an ORCID, a trusted publisher's identifier, a JST (Japanese Science and Technology Agency) identifier, or an NII (National Individual Identifier).

</contrib-group>
```

Use Cases

There are four basic steps for implementing ORCID identifiers, all of which require authentication as a core component. (1) **Collecting** validated ORCID iDs for individuals to ensure they're correctly associated with their affiliations and contributions. (2) **Displaying** iDs to signal to researchers that an information system is plumbed to support their use of ORCID. (3) **Connecting** information about affiliations and contributions to ORCID records, creating trusted assertions and enabling researchers to easily provide validated information to systems and profiles they use. And, (4) **Synchronizing** between research information systems to improve reporting speed and accuracy and reduce data entry burden for researchers and administrators alike (see <https://members.orcid.org>). Using these integration points, ORCID identifiers have been embedded in a number of different systems. Researchers are being asked to include their ORCID identifier when they submit a manuscript, dataset, or grant. Publication metadata repositories are ingesting ORCID identifiers and adding fields to search by ORCID identifier. Universities are providing faculty tools to link their local CRIS data with their ORCID record and the opportunity to synchronize data between the systems. Students are being asked to register for an ORCID identifier at the time of thesis submission. Data repositories have amended their metadata standards to include an ORCID identifier for dataset creators and contributors and are supporting linkages with ORCID records. Repositories are using ORCID identifiers as a means to maintain and update their holdings. External identifier systems are supporting cross-platform linkages between identifiers, supporting opportunities to review and validate algorithmically created name-based information clusters, and pass metadata between platforms. Altmetrics providers and research funders are leveraging ORCID registry data to support assessment of research impact. More detailed information on use cases is available at <https://members.orcid.org>.

CONCLUSION

The core issue underlying the ORCID initiative is the effective and appropriate identification of individuals who participate in the research community, and linking them with their research works, funding, and affiliations. Prior to the formation of ORCID, there were fragmented proprietary and discipline-based systems for uniquely identifying researchers, many of which are still operational today. In addition to providing a common identifier that can link existing researcher identifier systems, ORCID works with the community to ensure that the common identifier is embedded in research workflows and becomes part of the metadata associated with research

works, funding, and affiliations. It is the combination of these two ORCID mission activities—common open identifier and linking—that gives the community cause to believe that ORCID is a key component of solving the name ambiguity problem in research and scholarly communications. Solving this problem makes individuals more discoverable, assisting researchers in finding resources and collaborators to support their work. Linking the common researcher identifier with works, funding, and affiliations extends interoperability and supports reporting. At the individual level, this means improved discoverability and less time entering data on forms such as grant applications and postaward reporting, and at the

institutional level this means less time and more accuracy in identifying researchers and their works for workforce and outcomes evaluation reporting. Overall, the system interoperability supported by ORCID can lead to broader acknowledgment of research activities and the potential for expanding existing incentives.

Organization Theories

Evelyn Daniel

*School of Information and Library Science, University of North Carolina at Chapel Hill,
Chapel Hill, North Carolina, U.S.A.*

Abstract

The dominant paradigm of organization theory based on bureaucracy, open systems, and contingency theory is described with concepts traced to their historical roots. Parallel developments in public administration are also presented. This entry concludes with a consideration of network theories that have emerged in the latter half of the twentieth century as researchers consider groups of organizations rather than individual units.

For many years, organization theory has had a dominant paradigm based on bureaucracy, structural analysis, systems and contingency theory. This theoretical paradigm, usually called functional or rational, despite criticism from interpretative theory and critical social theory^[1] continues to be supported in schools and journals and to guide manager's decisions. Changes in the environment that reward speed and innovation have brought new networked organizational forms to the fore. These changes have affected both public and private sector organizations.

In this entry, I will take a more or less historical approach beginning as most organization texts do (Daft-Tsoukas^[2-9] (among others)) with a description of classical organization theory and then contrasting newer networked organizations to the classical model.

I have attempted to include theoretical writings from public administration that sometimes parallel and sometimes diverge from writings about corporations in the for-profit sector. Another article could be written about applications of these theories to the library and information world. Certainly libraries as large bureaucratic organizations are often involved in competition for resources and even existence. They confront issues of power and control, and have concerns about how to choose an appropriate structure (physical and social), how to integrate technology, how to socialize workers (professionals and nonprofessionals, full-time and part-time, career and contract workers), and how, when, and whether to enter into strategic alliances and joint ventures beyond their organizational boundaries. Libraries and other information agencies are good laboratories to study the interplay of forces described and predicted in organizational theory. However, the exigencies of time and space leave this task to others.

One fairly inclusive and often quoted definition of an organization by Hall^[10] is as follows: "An organization is a collectivity with a relatively identifiable boundary, a normative order, ranks of authority, communication

systems, and member coordinating systems; this collectivity exists on a relatively continuous basis in an environment and engages in actions that are usually related to a goal or set of goals" (pp. 22–23). Some of the qualities that define organizations often referred to in the literature include that a pattern of interaction has developed that is enduring and resists change, that there is a dominant and definable culture, that there is a hierarchical power structure that ensures conformity and provides control such that certain behavior regularities are more likely to occur than others.^[9] Over time, organization theory has come to embrace a fairly large domain. Lawrence and Lorsch^[11] argue that the heart of organization theory is the task of integrating and coordinating the components and domains of an organization including its environment, its strategy and decision-making processing, its goals and values, its culture, its structure, its authority and power relationships, its tasks, its communication processes, its people—leaders, teams, groups, and their individual motivations, work attitudes and behaviors.

Since Adam Smith^[12] first described the positive effects of work specialization and division of labor, organization theorists have wrestled with two primary opposing forces—differentiation and coordination. The more an organization divides labor into specialized tasks and separates departments, the greater the strain on communication and the greater the need for coordination or integrating mechanisms. As specialization increases and the complexity of the organization, so techniques of coordination must also increase. Even today with the potential of coordinating through electronic networks, the hierarchy continues as the dominant coordinating mechanism although there are signs that this is beginning to change.

Formal investigations of the organization qua organization began with Max Weber, who was born in 1864 and died in 1920. He wrote at a time when industrialization was affecting all facets of society and traditional authority structures were being challenged. Weber, a sociologist

defined and described the bureaucracy and called it the “ideal model” for an organization.^[13] He identified division of labor and the centralization of authority through hierarchy as two of its primary characteristics.

In fact, in one of the earliest of a continuing stream of criticism of Weberian bureaucracy, Merton in 1940^[14] observed that specialization (division of labor) and an emphasis on adhering to rules can lead to *trained incapacity*, in which employees find difficulty in dealing with situations that do not fit the rules or changes in rules and routines. *Displacement of goals* can occur in which people focus so much on following rules or on pursuing the goals of a simple department that the larger organizational goals as a whole are ignored. Victor Thompson,^[15] a public administration scholar in his book tellingly titled *Without Sympathy or Enthusiasm; the Problem of Administrative Compassion*, argued that Weberian bureaucracy can cause “bureaupathology” in its members who can become overly concerned with protecting the authority of their offices and too impersonal in their dealings with clients and other members of the organization.

Early writers on organizations built on Weber’s definition of bureaucracy and focused on technical rationality as the principal objective of an organization. This early period of organization theorizing is often referred to as classical organization theory. For example, Henri Fayol,^[16] a mining engineer, studied the problem of state public services and developed a theory appropriate to a wide range of organizations. He defined management as comprising five core functional elements: planning, organization, command, coordination, and control. He then outlined 14 fundamental principles of organization design, many of which are still considered valid today, are described below as tenets of classical organization theory. In 1937 Luther Gulick,^[17] a public administration theorist used Fayol’s theory and advocated dividing government work up into small specialized segments, allocating the work to those most skilled and coordinating it through supervision, clear task definition, instruction, and direction. Like Fayol, Gulick proposed a set of functions for the executive that form the acronym POSDCORB that, for some reason, has proved memorable to generations of management students. POSDCORB stands for planning, organizing, staffing, directing, coordinating, reporting, and budgeting.

By contrast, Mary Parker Follett,^[18] a consultant to government and business organizations, suggested that the same principles that create strong social communities could be applied to creating successful organizations of all kinds. In a startlingly modern formulation, she proposed a cooperative participatory process for giving orders in which supervisors and subordinates develop a shared understanding of the situation and what is required. This “law of the situation” foreshadowed ideas of workplace democracy and nonhierarchical networks of self-governing groups.

At the turn of the twentieth century, professionalization and the scientific method emerged. Efficiency became the

chief goal of both government and industry. Engineer and efficiency expert, Frederick W. Taylor^[19] urged a “scientific management” approach in order to learn the “one best way” to perform each task in the organization. The primary goal of the organization, according to Taylor and other proponents of the “organization as machine” model, was efficiency gained through research and task analysis. Taylor’s ideas met with bitter resistance on the grounds that work controls alienate workers and displace master craftsmen. Despite the furor, Henry Ford adopted Taylor’s principles for the assembly of automobiles. Later developments of total quality management (TQM) and business process reengineering (BPR) are considered direct descendants of Taylor’s ideas or Fordism, as it came to be known.

These ideas about organizations covered both public and private enterprises. Classic organization theory emphasizes rationality and efficiency, the importance of specialization and coordination, and asserts that the principles of classical organization theory are universal, “irrespective of the purpose of the enterprise, the personnel comprising it, or any constitutional, political or social theory underlying its creation” (p. 49).^[20] Writers in the 1920s and 1930s found attractive the idea of a strong chief executive vested with power and authority operating through an organization structure characterized by unity of command, hierarchical authority, and a strict division of labor. Dwight Waldo, a well-known public administration theorist, wrote “Democracy, if it were to survive, could not afford to ignore the lessons of centralization, hierarchy and discipline” (p. 200).^[21]

Woodrow Wilson, then a college professor, suggested in an often quoted paper^[22] that public administration should follow the model of business and that a government should establish executive authority, a controlling hierarchical organization, and have as its goal the achievement of the most reliable and efficient operations possible. The notion of the business model for government and nonprofit agencies, including libraries, with the primary goal of efficiency and an assumption of rationality continues today as a dominant theme in the study of organizations.

Classical theory of organization deals almost exclusively with the structure and design of the formal organization. The principles of classical theory are prescriptive for the rational structuring of organizations. Drawing upon early ideas from Fayol, the *functional* principle asserts that labor must be divided as the organization grows and that the division should follow clear areas of specialization. This leads to *departmentation* and the grouping of like activities into departments. The *scalar* principle deals with vertical growth in the chain of command through the dynamics of delegation of authority and responsibility. *Unity of command* ensures that a subordinate is accountable to one supervisor only. No gaps or overlaps in authority jurisdictions among the positions in the chain of

command should exist. The resulting shape of the organization structure becomes the familiar pyramid.

The *line-staff* principle addresses the proper relationship between specialists employed for their technical expertise and the people with central decision-making authority (“the line”). The distinction between line and staff comes from military organizations and dates back to antiquity. The potential of conflicting authority between line and staff is recognized in classical organization theory and resolved by stipulating that the staff may advise and facilitate line work but may never command the line; only those with formal legal authority may do so. We see this principle in public administration theory as well. The line-staff division is most clearly seen in the emphasis by Wilson on the distinction between politics and politicians (here equivalent to the line of command) and public administration and administrators (equivalent to staff support in an advisory capacity).^[23]

Span of control refers to the number of subordinates a manager can effectively manage. When people are added to an organization the result can either be a wide span of control and a relatively flat structure or a short span of control and a tall structure. Classical theory favored close supervision and recommended that a supervisor have responsibility for no more than four to six direct reports. The more various the work, the fewer people are to be supervised and conversely, the more similar the work of those supervised, the more people a supervisor can oversee.

Today, the structural approach to organizations is still the aspect to which most space in organization texts is dedicated. Probably the most well-known and thorough description of the structure of an organization comes from Mintzberg^[24] who provides a comprehensive review summarizing the structural alternatives that managers can choose among. Galbraith^[25] also described strategic choices in organization design. Mintzberg’s scheme for describing organizational structure identifies five major components: *the operating core* where members perform the basic work of the organization, *the strategic apex* where the top positions reside, *the middle line* for those managers who link the apex to the core through supervision and implementation (hence the term “middle managers”) and two types of staff units: *the technostructure*, where analysts work to standardize work, output, and skills, and *the support staff* who provide support to the organization outside the work flow of the operating core, for example the mail room, food service, public relations, the library, legal services, and the like. Often these latter units are considered the first candidates for outsourcing as they are not essential to the work of the organization.

According to Mintzberg, organizations establish structures to divide and then coordinate work within and among these five components through the use of four different structural design tools:

1. *Positions* through the use of job specializations, behavior formalization, training, and indoctrination.
2. *Superstructure* or departmentation through unit groupings based on knowledge and skill, function, time, output, clients, or place. Grouping choices can follow workflow among departments or join people working on common processes or one can group by scale (large units need their own functional categories); groupings can even be created to facilitate social relations, morale, and cohesiveness.
3. *Lateral linkages* through performance-control systems, action-planning systems, and liaison devices.
4. *Decision-making systems* through decentralization either vertically by pushing decision-making authority down or horizontally by spreading decision-making authority out to staff analysts, experts, and other individuals involved in the work of the organization.

Mintzberg also proposed a typology of five kinds of organization structures based on their choice of these design elements. The five structures begin with *simple structures* for new and small entrepreneurial organizations with vertical and horizontal centralization and coordination by direct supervision at the apex. Mintzberg identified two types of machine *bureaucracies* that are elaborations of simple structures that have evolved through growth, age and/or external control. These organizations employ a standardizing technostructure for work processes, experts, and staff specialists. *Public machine bureaucracies* are required to standardize their operations for political reasons. *Professional machine bureaucracies* are those organizations where professionals dominate the operating core, decentralization is general, and coordination is via standardization of skills. These machine bureaucracies may further evolve to divisionalized forms with product-oriented subunits each with its own manufacturing and marketing units. The final kind, Mintzberg calls the *ad-hocracy*. It is organic, innovation oriented, greatly emphasizes fluid communication and flexibility and is decentralized into design teams. The ad-hocracy may be seen as a forerunner of some of the newer networked and virtual organizational forms to be described in the last section of the paper.

To return to the historical thread, in the 1930s a reaction to the dominant classical organization theory was provoked by some experiments performed at the Hawthorne plant of the Western Electric Company that demonstrated the importance of human motivation on the expenditure of effort in an organization and shifted the attention of theorists away from the structure and design of the organization to a focus on the employees within and relationships among them. Workers were more than “hands” but had “hearts” (feelings and attitudes that affected productivity). Norms or implicit rules of work groups affected productivity.

Charles Barnard,^[26] an American industrialist and telecommunications executive, developed a theory of

management and organization that he called a cooperative system. He observed that human physical, psychological, and social limitations forced people to enter a “cooperative contract” in order to achieve goals that they could not accomplish alone. Having agreed to cooperate, the range of individual freedom to act autonomously was reduced and the domain of joint action was enlarged. Independence was sacrificed (or traded off) for greater material and social satisfactions from the cooperative effort. Barnard saw the problem of maintaining the cooperative spirit once the cooperative contract was formalized as the primary task of the manager. His ideas echo those of Mary Parker Follett.^[17]

Barnard asserted that the manager needs to develop a deeper understanding of the organization and its employees by drawing upon the behavioral sciences. Organizational rationality, he argued, results from the manager’s conscious effort to create a cooperative system by continually maintaining an equilibrium between organizational goals and individual employee goals. Barnard’s one book, *The Functions of the Executive*,^[26] remains an influential work calling the manager’s attention to the importance of social and psychological factors in motivating workers. Motivation and the culture of the organizations continue to be major topics within organizational theory.

Some examples of often cited early theorists who write about motivation include Maslow,^[27] Herzberg,^[28,29] McGregor,^[30] and McClelland.^[31] Maslow’s theory of human needs and motives first advanced in the mid-1950s may be the best known motivation theory. People continue to find the theory appealing even though research validation is lacking. Maslow held that needs and motives fall into a hierarchy ranging from lower order to higher order needs. *Physiological needs* (food, shelter) are lower order, followed in ascending steps by *safety and security*, *love and belonging*, *status and self-esteem* and at the highest level, *self-actualization*. The needs at each level, according to Maslow, dominate until satisfied and then the individual can focus on the next level of need.

Herzberg’s two-factor theory of motivation,^[28] distinguishes between what he terms *hygiene factors* that are extrinsic and cause dissatisfaction, like working conditions and rewards, and *motivating factors* that are intrinsic and relate to interest and enjoyment of the work itself accompanied by a sense of growth and achievement. Other researchers argued that the methods used to develop Herzberg’s theory (self-report of events leading to satisfaction or dissatisfaction) may have skewed the findings because of a social desirability effect in which the participants may have provided what they felt were the most socially acceptable responses.

McGregor^[30] divided managers into two types: Theory X and Theory Y. The theory X manager sees workers as passive requiring management and motivation and direction; theory Y managers take advantage of higher order needs and build on the worker’s capacity for self-motivation and

self-direction. Many current writers on motivation theory focus on theory Y concerns and advocate for a human investment philosophy.

One of the most enduring and well-supported theories on motivation is David McClelland’s^[31] grouping of people into three categories depending on what is the primary motivating factor: the need for *achievement* (to master one’s environment and to successfully accomplish tasks based on one’s own abilities), the need for *power* and control over oneself and others, and the need for *affiliation* (the desire for friendly relations with others). McClelland concludes that the most effective managers develop a high motivation for power but with an altruistic orientation and a concern for group goals. He adds that too strong a need for friendship (affiliation) can hinder a manager.

Current emphasis on work motivation emphasizes process more than content. Expectancy theory, for example, asserts that an individual performs a mental calculation summing up the desirability to him/her of all the outcomes that might result from an action with each outcome weighted by the probability of its actually happening. The rational individual will do what he/she perceives will most likely result in the most good and the least bad.^[32] Social learning theory blends behavioral ideas from operant conditioning (positive and negative reinforcements provided on some schedule either fixed or variable) with cognitive processes like goal-setting and a sense of “self-efficacy” or personal effectiveness.^[33,34]

The approach to organizations that focuses on motivation and uses social psychology is often called the human relations approach. Effectiveness is measured by the commitment, cohesion, and good morale of the employees. A strong focus is placed on participation, conflict resolution, and consensus building. Teams are emphasized and there is a belief that involvement leads to commitment.^[35]

Leadership and group processes in organization have also received substantial theoretic attention in the study of organizations. Studies on the traits of effective leaders at Ohio State in the 1950s led to the observation that leadership behavior was more important than any particular trait. Two dimensions of leadership behavior have been singled out: *consideration* or a concern for people and *initiating structure* or a concern for production. Blake and Mouton^[36] developed a managerial grid based on these two dimensions as an approach to improving management practice. They urged managers to strive for high levels on both factors.

In reaction to too great an emphasis on the qualitative aspects of the work in organizations, Herbert Simon^[37] attacked these principles as too vague and contradictory. Simon followed up with a book, *Administrative Behavior*^[38] focused on decision-making. Simon observes that managers are less rational than theorists assume. Decisions are limited by the number of variables our brains can handle, the time available, and our reasoning powers so that decisions are made under conditions of bounded rationality. Simon

invented the term “satisficing” to describe administrative decision-making behavior in selecting the best available alternative after a limited search using simple heuristics or rules of thumb. Simon’s work on bounded rationality and satisficing challenged the assumptions of the rational man economic theory and won him the Nobel Prize in economics in 1978. Cyert and March^[39] provided evidence in support of Simon’s observations in a study of business firms reported in *A Behavioral Theory of the Firm*. March and Simon’s 1958 *Organizations*^[40] book provided a more elaborate conceptual framework with hypotheses about behavior in organizations, especially about an individual’s decision to join an organization and to participate actively within it.

Using this conceptual framework, the Tavistock Institute in Great Britain began conducting research on “socio-technical systems” emphasizing the close relationship between technical and social factors in the workplace.^[41] This ushered in a new model of the organization as an open system. It drew heavily on general systems theory as described by biologist Ludwig von Bertalanffy.^[42] He envisioned an overarching theory that would govern all living phenomena from molecules and cells up to individuals, groups, and society. To generalize across all these elements he referred to each phenomenon as a system with mutually interrelated parts that affect each other and depend upon the whole. Kenneth Boulding,^[43] an economist, outlined a hierarchy of systems from the simplest that he called *frameworks* (e.g., lists, indexes, anatomies) through nine levels to the *transcendental* (metaphors and esthetics). His level 4 included living things which he called “open systems.” These were characterized by input of energy, throughput of materials, reproduction, and self-maintenance.

Open systems theory became popular in part due to the rapidly changing environment of the mid-1960s. Two aspects were key. First, each different part of the organization was seen as interdependent on the other parts, and second, the external environment affects the way an organization performs.^[44] The open systems perspective for organization theory was most fully developed by Katz and Kahn^[45] who used general systems theory as a broad framework for conceptualizing the organization as an open system with inputs, throughputs, and outputs. They stated that the organization has *equifinality*, that is, the same outcome can be achieved by different means. *Negative feedback* enables the organization to adapt and innovate in order to continue to acquire needed external resources. The internal regulatory mechanisms within an organization must be at least as diverse and complex as the environment in which it operates (“the law of requisite variety” appropriated from cybernetics).^[46] In analyzing the processes in the throughput, Katz and Kahn distinguish three major subsystems—maintenance, adaptive, and managerial. The vision of the organization as an open

system adapting to a variety of influences and imperatives suggests that the “fit” between the organization and its environment and between the organization structure and its dominant technology is central.

Burns and Stalker^[47] argue that effective open systems organizations must adapt their structure to contingencies. They propose that successful organizations are either *organic* or *mechanistic*, depending on the environment in which they function. Successful mechanistic organizations operate under stable conditions with a high need for consistency and specificity and are bureaucratic. Organic institutions are more fluid and able to adapt to rapidly changing environmental or technological conditions. In the organic organization, greater emphasis is placed on networking and lateral communication rather than on hierarchy; superiors act as facilitators.

Formulating a contingency theory of organization structure, Lawrence and Lorsch^[11] studied U.S. firms in three different industries where they confronted varying degrees of uncertainty, complexity, and change. More uncertainty and turbulence in the surrounding environment meant more differentiated internal structures (different goals, time frames, and work cultures). The more differentiated firms, as one might expect, also had more elaborate structures for integrating diverse units. Organizations in more stable environments showed less differentiation and integration.

James Thompson^[48] further developed the contingency perspective drawing on Herbert Simon’s ideas about bounded rationality and consistency. Thompson presented his work as a series of propositions about how the rational organization will use hierarchy, structure, and buffering units to isolate the technical core in order to provide stable conditions for the work of the organization. He suggested that the organization will group subunits based on its need for information exchange during the work process. When organizations confront a shifting unstable environment, Thompson hypothesized they will adopt a more decentralized structure with fewer rules and procedures. A decade later, Mintzberg^[49] echoed this proposition with his assertion that the more complex the structure, the more decentralized the structure, all things being equal.

One school of thought with the central thesis that organizations are limited in their power to adapt to their environments is called “population ecology.”^[50] Here the emphasis is on groups of organizations that are “selected” for survival on the basis of adaptation and “fit” between their structure and the environmental characteristics. In this theoretical framework, the environment is the determinant of effectiveness which explains why organizations in similar environments have similar structures. As the environment changes, different structural variants become more fitting and previously selected characters are selected out. The organizational environment has a saturation point beyond which it cannot support more organizations, so claim Hannan and Freeman.^[51]

Robert Quinn^[52] attempted to combine four of the main streams of organization theory into what he called a “competing values” framework. The four streams he selected were scientific management from Taylor in the late 1800s, administrative theory from the 1920s with Fayol and Weber’s ideal bureaucracy. The third stream was the human relations school from the Hawthorne studies of the late 1920s and 1930s and Barnard’s writings. The fourth stream was the decision-making school described by March and Simon in the late 1950s. In the Quinn framework there is no “one best way” to manage in all situations but effective leadership varies according to the particular situation. The two key dimensions that predict the appropriate managerial style are first, the continuum between flexibility (innovation) and control (prediction, order, stability) and second, the continuum between emphasis on the organization (concern for productivity, systems) and emphasis on people (concern for people).

Another primary concept of organization theory is the organization life cycle. Every organization seems to pass through the same stages on the way to maturity. Haire^[53] suggested that a biological metaphor could be used, (see above for biological metaphors for open systems and for sets of organizations selected for survival). The life-cycle approach has some key assumptions. There are distinct stages through which an organization progresses; the stages follow a consistent pattern and the transitions from stage to stage are predictable. Based on age, size of the organization, and growth rate for the industry, Greiner^[54] proposed five phases, each stage having a specific management, style, and a dominant problem whose solution initiates the next stage. Phase one is marked by *creativity*. The organization is young and has an energetically committed leadership and resourceful employees, all dedicated to the mission. Communication is frequent and face-to-face. A leadership crisis emerges because the owner-founder’s competence is often technical rather than managerial. Phase two is marked by *direction* under the leadership of a capable business manager who creates a functional structure and reporting requirements, puts a hierarchy in place, and hires specialists. As things become more formal and systematized, a crisis of autonomy emerges. Lower level employees feel encrusted in red tape and want more initiative. This leads to *decentralization and delegation* allowing the organization to expand in many directions; this, in turn leads to a crisis of control and the need for coordination. The fourth coordination phase uses *formal systems* to promote integration often through databases and formal planning procedures. A proliferation of systems leads to a crisis of red tape solved by a fifth *collaborative* phase in which project teams are initiated, problem-solving task forces are created, and more collaboration is encouraged. Social control, personal responsibility, and self-managed teams tend to replace formal control systems. Greiner suggests the crisis at this stage may be “psychological saturation” or burnout and

provides a few strategies to deal with it. The main message is that no solution is permanent as the characteristics of the solution often breed new problems.

Other life-cycle models are similar suggesting that an organization is formed, grows, matures, and then declines or possibly undergoes radical change and renews itself. Organizational learning is one way for the organization to move away from inevitable decline. Argyris and Schön^[55] define learning as the ability to detect and correct errors, which they define as a mismatch between intention and outcomes. They identify two kinds: single-loop learning (improving strategies to reach a goal) and double-loop learning (questioning the fundamental assumptions and values of the organization). They define organization learning as a preference for double-loop learning and the will to implement it.

W. Richard Scott^[56] in summing up the changes in the field or organization studies asserts that the introduction of open system models provided the impetus for a search out into the environment to identify the determinants of organizational structure. Contingency theory predicts that the variation in the complexity and uncertainty of an organization’s environment leads to “best fit” organization structures. Resource dependence theory also focuses on adapting organizational structure to the environment. It emphasizes political as well as economic dependencies based on the fact that an organization must exchange resources in order to survive and that, in the exchanges, power differences arise. Thus, managers must not only adapt their organizational structure to the environment but must try to act on the environment reducing dependencies in order to see advantages in power relationships.^[57]

Network theory has also emerged as a powerful explanatory tool and methodology to measure the relationships of organizations within a network.^[58] The location of an organization within a network and the structure of the network affect behavior and decisions within an organization.^[59] Hannan and Freeman^[60] argue that researchers should shift attention from the individual organization to a set, or population, of organizations of the same type, because, according to these theorists, fundamental change affects all organizations of the same type in an approximately equal way. Just as the life cycle approach to organizations (described above) follows the birth, growth, maturity, and decline (or renewal in a new form) of a single organization, so in the population ecology approach groups of organizations of the same type are examined over long periods of time in a similar way from birth, growth, maturity, and decline (or renewal as a new type of organization).^[61]

Research in organizations today focuses on a set of similar organizations and their resource exchange partners as the appropriate unit of analysis. This allows concentration on resource dependence relations and organizational strategy by looking at exchange partners, funding sources, competition, and regulations.^[62]

The shift to open systems and the emphasis on looking at populations of organization within their exchange environment reveals that the boundaries of organizations have become less stable and fixed. Organizations now employ more temporary, part-time, and contract employees so that the concept of membership in an organization is less meaningful. Individual firms merge or split off components; they enter into alliances and partnerships creating new, often temporary organizations.

In the past organizations tended to absorb environmental challenges through adding workers, technologies, and technical expertise as well as incorporating sources of inputs and marketing and distribution systems, thus growing in size and scope over time.^[63] Today organizations have moved in the opposite direction shedding personnel and units and contracting out functions that were formerly performed in-house.^[64]

Miles and Snow^[65] describe the dynamic network—a group of organizations, partnerships, and/or individuals who subcontract their services to a “broker” core that provides coordination, supervision, and control of a given project. The networked organization keeps human relations and overhead low while increasing responsiveness to customers. They describe the network organization as “delayed, highly flexible, and controlled by market mechanisms rather than administrative procedures” (p. 4).

Galbraith^[66,67] contends that all organizations today need to develop lateral capability, that is, ways of coordinating different functions with other functions that need to communicate with throughout the organization. He describes three types of lateral linkages: across functions, across business units in a diversified corporation, and across countries and regions for global firms. Horizontal structures are sometimes called *process structures* while network structures are *organic* and increase lateral capability.

Horizontal organizations are flat structures with minimal layers of management and self-managed, multidisciplinary teams organized around a core process. The primary goal is customer satisfaction, which is attained by reducing the boundaries with suppliers and customers and by empowering employees. Teams are the central organizational building block and they manage themselves. Members are rewarded for skill acquisition and team performance. The benefits include lower management costs, more widely shared communication and decision-making and greater employee involvement. Decision-making is more rapid. The disadvantage is figuring out how to define the numerous processes in most organizations. The design is most appropriate in companies with short product life and development cycles where customer satisfaction is the goal and the environment is uncertain.

Four major design features of the new organizational forms are: 1) *vertical disaggregation*—major functions like finance, product design, and manufacturing are performed by independent organizations and tied together

in a network; 2) *brokers*, who facilitate linking, locate potential partners, and coordinate the separate aspects; 3) *market mechanisms*—work is by contract and payments are based on performance; (4) *full-disclosure information systems*, which become important in mutually and instantaneously verifying individual contributions.

Walter Powell^[68] asserts that today’s economy resembles a Web and not a hierarchy and “to force technologies that enhance ‘networking’ into a pyramidal form serves only to constrain their effectiveness” (p. 502).^[69] He argues that the impact of the rapid growth of new information and communication technologies is changing the way work is constituted and the way organizations are structured. One big change is the shift in conceptualizing work from *jobs* to *projects*. Jobs have been the standard way to package work for the last two centuries and are suitable for situations where the same tasks are done repeatedly. The emerging form of work organization is a team or work group charged with responsibility for a project. The activities of the team are coordinated by iterated goal-setting as the group members learn through monitoring the partial results of their work.^[70] The project form of work organization integrates design and production and rewards productivity rather than seniority. Thus, according to Powell, the conception of work has changed from a focus on specific tasks carried out by individuals and constrained by rules and standard operating procedures to a collective effort conducted by teams with diverse skills and considerable discretion who are judged by results.

The change in the organization of work causes the rise of the networked organization where the firm is “an intricate latticework of collaborations with outsiders” (p. 507).^[71] thus blurring the boundaries of individual organizations. Harrison^[72] states that the new networked firms have four key components: 1) a core-ring structure in which there is a group of highly paid, highly skilled employees and everyone else is relegated to a lower cost periphery; 2) new information technology is used to coordinate widely scattered activities for just-in-time production; 3) extensive use is made of subcontracting, especially across national boundaries for lowest cost work; and 4) the firm uses various measures to attempt to gain greater commitment from the most expensive-to-replace employees. Powell et al.^[73] examined the biotechnology and pharmaceutical industries and concluded that centrality is key and that a firm grows by becoming a player and not vice versa. Speed is also important. Brown and Duguid^[74] point out that the core task of organizations today is to access knowledge rapidly and turn it into tangible products.

The not-for-profit organizational side has also been affected by these deep structural changes although perhaps less so. Public and private organizations remain different in goals and operation, so the movement in the direction of post-bureaucracy is more limited. Traditional bureaucracies

continue to exist in government and not-for-profit agencies, but we also see an array of public-private partnerships with many services that are contracted out.

The new public management movement has encouraged a shift toward government by network and government by market.^[75,76] Fiscal authority measures and efforts to improve public productivity led to experimenting with alternative service delivery mechanisms in the public sector, including contracting out and privatization. These ideas were captured in Osborne and Gaebler's 1992 book, *Reinventing Government*.^[77] These writers provided 10 principles for what they called "public entrepreneurs" to bring about massive governmental reform. These principles are at the core of what is called the "New Public Management," and include introducing competition among public, private, and nongovernmental service providers, injecting the concept of profit into the public realm through charges and fees for public services, using information technology and improved communications systems to decentralize government and shaping the environment to create a market.

Reinvented government praises competition, flexibility, employer empowerment, and customer service. Central control mechanisms are reformed and performance measures introduced. An ethos of innovation, experimentation, and cross-agency work replaces the ethos, according to one proponent of reinventing government.^[78] Critics of the government by network call it a "hollow state,"^[79] in which a government agency relies on others (firms, nonprofits, or other government agencies) to deliver public services jointly and no one knows how to manage these networks.

In government by market, the government uses state power to create a market that fulfills the public purpose. For example, in order to control pollution, one might require polluters to pay for their right to pollute. As in the private sector, we see decentralization and empowerment of individual government agencies (now called "business units") to create own objectives. Through the use of information and communication technology, the staff is controlled less by regulation and more by market and customer measures. Hierarchy and rule-based controls are replaced by such market-type mechanisms as benchmarking for best practice, setting targets, and using service-level agreements.

Critics of the network and market governance models^[80] predict that these newer organizational forms that are intended to make government more flexible and responsive and less hierarchical may have unintended dysfunctional consequences. Growth in centralized monitoring can lead to a decline in trust and collegiality. Bureaucracies represent some positive values, such as impartial conduct, due process, separation between public and private, between the role and the person. Some of the restructuring of work described above can lead to problems on the human relations front. As boundaries become more permeable, roles

more flexible, there will be fewer career paths and rewards for loyalty and conformity to standardized organizational obligations. The "portfolio" worker becomes reliant on his/her own human capital and knowledge and exists outside the corporate hierarchies. Post-bureaucratic theorists need to consider alternative ways of holding organizations together. Presumably cultural and other indirect means of cooperation replace rapidly disappearing middle management. Even within the organization, units are compelled to serve as customers in simulation of market disciplines.

Denhardt and Denhardt^[81] have proposed an alternative to the new public management which they call the new public service. This alternative draws on more humanistic traditions, such as interpretive theory (phenomenology), critical social theory, and postmodernism. In this view, the individual is not seen as a customer but rather as a citizen who looks beyond self-interest to the larger public interest. Even as the rhetoric speaks to new networked organizations with responsibility devolving to self-managed teams, there is a counter trend that appears equally strong. In the fast food and retail industries and in call centers operations incorporate classic organizational processes. The service encounter is standardized and employees must learn scripted language and behavior. They work in continued high surveillance via technology and customer monitoring. Even in organizations embracing knowledge management, networks, and communities of practice, there is parallel work in codification, storing, and distributing the commodified knowledge and many rules for using these databases.

What does the future hold for theories of organization? The purely rational approach has been softened and added to by an understanding that decisions are made on the basis of human emotions and intuitions.

It is best to see the forms assumed by contemporary organizations as a series of hybrids often with hierarchy concealed behind more complex forms of coordination and control.

Organizational Culture

Gunilla Widén-Wulff

Information Studies, Åbo Akademi University, Åbo, Finland

Abstract

The literature covering organizational culture is broad and there are many angles and perspectives, different fields of study, schools of thoughts, and theories covering the subject. In this entry, organizational culture is first described through the historical influences with some general definitions and categorizations. Furthermore, organizational culture is described from an information and knowledge perspective, giving information resources a cultural dimension. Finally organizational culture is presented in the library context and some reflections on the assessment of organizational culture are given.

INTRODUCTION

Organizations may be described from many different points of view, depending on what one chooses to emphasize. Organizations can be viewed from environmental, cultural, or social perspectives. The physical structures and the technology of an organization can be focused and there are different metaphors to use as a starting point. In his 1986 book, Gareth Morgan introduced a set of metaphors to describe different perspectives of organizations (e.g., as machines, organisms, political systems, and cultures).^[1] These images have been valuable tools when talking about complex phenomena within organizations. The image of organizations as cultures can be used as an umbrella concept when approaching organizations from cultural and symbolic points of view. Organizational culture is a way of understanding an organization in all its richness and variation (p. 2)^[2] but is at the same time very complex and includes subcultures, information cultures, etc.^[3] Organizations consist first of all of individuals shaping together a unique context. This means that every organization has its own unique organizational culture. The culture of an organization is a mix of values, thoughts, and traditions of the people in the organization (p. 5)^[3] and the organizational culture sets the framework for what is expected and how things are normally done, and supports the organizational goals and aims.^[4] Organizational cultures carry systems of meanings shared to various degrees that help the members of the organization to collaborate without having to define or contextualize their action constantly (p. 2).^[2] Using the organizational culture metaphor brings forward useful information on intangible assets and explains informal behavior and activities of an organization. On the other hand, this metaphor generates a fairly general picture, covering many aspects, and might become vague in its meaning.

The literature covering organizational culture is broad and there are many angles and perspectives, different

fields of study, schools of thoughts, and theories covering the subject. While there are a wide range on meanings and perspectives, this entry starts by briefly looking at the historical influences on the organizational culture perspective and thereafter describe the information and knowledge perspectives within the organizational culture context, and how organizational culture perspectives are used within Library and Information Science.

INFLUENCES ON ORGANIZATION CULTURE

The development of studying organizational culture has its origin in many different perspectives and fields of study. In the 1980s, a shift from the more static and system-oriented perspectives toward the perspective of organization's as cultures^[2,5] began to emerge from success stories of Japanese companies as well as big companies in the United States.^[2] The main themes of this cultural perspective are based on anthropological studies and symbolic aspects,^[6] the sociological perspective, and aspects of social construction of reality,^[7] and the management perspective looking at the social psychology of organizing.^[8]

Through the anthropological perspective, studies on organizational culture have been inspired to look at language, rituals, and social structures.^[9] The symbolic cultural theory identifies culture as a system of common meaning and symbols. For example, a company culture consists of values, norms, and symbols shared by the employees in the company. These are shaped within the company's process of surviving external challenges and demands while striving to keep its internal stability. These values and norms are actively shared by the members of the company, shaping the culture that creates continuity and behavioral structures.^[10]

The influence of organizational sociology is very broad and direct. According to the sociocultural perspective,

culture is a component in the social system and relational and structural perspectives are highlighted. Organizational life has been studied through numerous sociological studies with the organizational culture as the basis.^[9] Many researchers have described the organization as a micro-society where the structures and systems are the same as those existing in the society.^[11] The sociological perspective has also been combined with social psychology, which is connected to cognitive viewpoints and organizational climate. Representatives of the cognitive viewpoint are, e.g., Witkin and Goodenough (p. 57)^[12] and according to this theory, culture is a result of common processes of thoughts. Studying events, behaviors, and feelings of the organizational culture may be pictured and it gives a possibility to reveal whether everyone has the same way of thinking or if different subcultures can be identified. The difference between the social and cognitive perspective to organizational culture lies in the question whether culture is something an organization has, or what an organization is.^[5,13] If organizational culture is a possession or a definition of the organization has also managerial implications. While culture has long been a strategic tool in business organizations it is important to clarify which perspective is more important for the particular organization.

Apart from the many existing theories concerning cultural influence, there are also several dimensions and layers of the culture to take into account. Culture is not an isolated variable affecting the organization. On the contrary, it is always integrated into many other areas of organizational understanding.^[10] A way of mapping the understanding of organizational culture is to use schemes and dimensions. Quite a useful model and definition is the one by Schein^[14] who says that culture is “a pattern of basic assumptions—invented, discovered, or developed by a given group as it learns to cope with its problems of external adaptation and internal integration—that has worked well enough to be considered valid and, therefore, to be taught to new members as the correct way to perceive, think, and feel in relation to those problems” (p. 9).^[14] He then distinguishes three levels of culture. The first and most visible level is artifacts and creations including the written and spoken language and the behavioral patterns of the members of a group or organization. The second level is described through values reflecting the sense of how to deal with problems and unpredicted action. Most values are conscious and serve as the normative function, guiding members in how to deal with situations. The third level, basic underlying assumptions, is reached when a solution to a problem has worked several times and it becomes the pattern of how to deal with it. When something becomes this taken for granted there is little variation within the cultural unit (p. 14–18).^[14] According to Schein’s definition the underlying assumptions are at the core of organizational culture and communicated through values and artifacts. This definition is

further developed by Hatch^[15] who integrates dynamics of symbols and processes into organizational culture. This is done in order to obtain a more holistic picture of how culture is formed by assumptions, values, artifacts, symbols, and the processes that link them.

Another important way of categorizing organizational culture is through the dimensions introduced by Hofstede (p. 188).^[16] Through a large research project across 20 organizational units in Denmark and the Netherlands in the 1980s, Hofstede identified six independent dimensions of practices which play a role in determining the organization’s culture:

- Process-oriented versus result-oriented;
- Job-oriented versus employee-oriented;
- Professional versus parochial;
- Open systems versus closed systems;
- Tightly versus loosely controlled; and
- Pragmatic versus normative.

Identifying where an organization stands in these dimensions makes it easier to manage the organizational culture.

A third example of defining different kinds of organization cultures is Wallach’s^[17] identification of bureaucratic, innovative, and supportive cultures. The bureaucratic culture is based on systematic thinking, clear division of responsibility and power, with business activities based on long traditions. The innovative culture is alert to changes and flexibility, whereas the supportive company culture strives to create a safe environment for the personnel where there is no need to be afraid of changes.

These kinds of categorizations, dimensions, and layers of organizational culture are important managerial tools. Identifying and understanding the organization’s culture makes it easier to adjust the organizational activities to change and respond to challenges, or other kinds of activities to fit the particular organization and its members.

DEFINING INFORMATION CULTURE AS A PART OF THE ORGANIZATIONAL CULTURE

During the 1990s there was a shift in the literature on organizational culture toward dynamic perspectives that underlined the individuals in a social context^[18–20] targeting aspects of learning and knowledge creation,^[18,20,21] with a further focus on innovation^[4] and performance. Managing information and knowledge as important assets became important perspectives especially in information science research (p. 88).^[3] In the following section, the role of organizational culture is discussed from an information management (IM) and knowledge management (KM) perspective.

When the concept information culture is discussed in the literature, we are often reminded of the fact that every company has its unique information culture. There are

several factors affecting the information culture and several layers of information behavior to take into account. Wilson^[22] shows that individual information behavior is affected by psychological, social, and environmental variables, and consequently the organizational information behavior is a result of constant interaction between individuals in a social and cultural context. Knowledge is created through human interaction which means it is a cultural product. In organizations, one finds networks of people interacting which are not visible on the organizational chart. It is therefore important to recognize these networks in order to manage knowledge effectively.^[23]

The function of information culture is about having access to information as a resource for reaching organizational aims. Information culture is responsible for unwritten and tacit behavior and fills the gap between what has officially happened and what really happened (p. 24).^[24] Its function is also to maintain the balance in the social system and create meaning and contents. The information culture focuses more specifically on cooperation, communication, and information behavior in general in the organization. Information culture can be defined in many ways. On a general level information culture could be defined as "... a context in which needed information is communicated so that the company has the greatest possible use of internal and external information. This culture consists of individuals, traditions, systems, and values. The aim is to show how these factors together create the context in which the information is regarded as an information resource for fulfilling corporate goals" (p. 32).^[25] Information culture is often also defined from a more specific information technology perspective: "a culture in which the value and utility of information in achieving operational and strategic success is recognized, where information forms the basis of organizational decision making and Information Technology is readily exploited as an enabler for effective Information Systems" (p. 94).^[26]

Different kinds of information cultures provide different solutions for handling quick changes and challenges in the information intensive society. In a study of the information culture in Finnish insurance businesses it was shown that information, as a resource in an organization, should be supported by an open and active information culture. While there are different kinds of information cultures among the insurance businesses and they adapt differently, it is important to know what kind of culture exists in the company in order to adjust the information work and planning accordingly. Open, changeable companies, where integration of processes and functions are working well, can more easily shape an active information culture. That means that the planning of processes like production and marketing is strongly integrated and a company is able to create overall solutions for the whole company. Because of the integration of the processes, a more active communication between the units is created^[25] with effective knowledge-sharing as a goal.^[27]

Actual information use in the workplace is shaped by the organizational culture^[25,27-29] through its influence on the organizational values. Knowledge about existing information culture and information infrastructure enables a more effective implementation of IM strategies and makes KM an important part of cultural management.^[30,31]

As mentioned earlier the categorization of organizational cultures is a usable managerial tool. This has also been shown in the context of integrating KM practices into the organization. Among others Leidner, Alavi, and Kayworth^[32] have examined how different kinds of cultures influence the KM practices. For example, a bureaucratic culture^[17] favors an initial process approach to KM. An innovative culture^[17] enables groups in organizations to develop KM practices useful to their group. Cooperative cultures^[33] enable more process-oriented and practice-oriented KM activities as well as creation of different communities of practice around KM, while individualistic cultures^[33] inhibit sharing, ownership, and reuse of knowledge.

An important premise of the knowledge-based view of the firm is that organizations exist to create, transfer, and transform knowledge into competitive advantage.^[34] When a KM culture is the goal it is important to make knowledge sharing a norm in the organization. In reaching a KM culture it is important to encourage people to work together effectively and collaborate.^[3,6] When people collaborate they try to clarify each other's knowledge, which means that they interpret codified information and vague perceptions of implicit knowledge, which eventually will correspond to one's expectations (p. 222).^[35,36] This means collaboration is not always a very straightforward process and when aiming at effective knowledge sharing it is important to create a culture of trust, respect, recognition, reward, and interactivity (90-92).^[3] Cultural enablers and barriers to knowledge sharing are however often invisible and difficult to grasp. The visible dimensions of culture such as values and missions, structures and stories, should then be balanced with the invisible dimensions of culture such as unspoken sets of core values. This means that the awareness of cultural dimensions and widely held core values helps to link knowledge sharing efforts with the common interest. Visible connections between knowledge sharing and practical goals are then possible to make and the holistic view of persons working closely, techniques, and technology is important.^[28,37,38] In the end, overcoming the cultural barriers to sharing information and knowledge has more to do with how one designs and implements one's management efforts into the culture than with changing the culture.^[28]

ASSESSMENT OF ORGANIZATIONAL CULTURE

Cultural analysis includes a variety of possible perspectives in a multidimensional context. Alvesson (p. 189-190)^[2]

suggests some principles for the productive use of the culture concept.

- The cultural concept should be related to specific events, situations, actions, and processes.
- Culture should be treated as a network of meaning guiding feeling, thinking, and acting rather than an external force. Meanings should be viewed as processual and situated, not as a fixed essence.
- Cultural interpretation should be sensitive to variation and contradiction.
- It is also important to relate the understanding of culture to power and how power operates in social relations.

These principles can be realized both theoretically and empirically. Theoretical studies of organizational culture include both macro- and micro-perspectives. When looking at organizational culture from a macro-perspective, culture is usually interpreted as a consequence of the needs of the firm. Rites and ceremonies are studied and different types of cultures and subcultures are identified (e.g., productive, bureaucratic, professional, closed, open). The micro-perspective is more concerned with the psychological point of view, attitudes, and behavior. Usually the studies look beyond the surface, and culture may be assessed from a psychoanalytical perspective going deeper into meaning and structures.^[9]

Empirical studies of organizational culture can mainly be divided into three categories: holistic studies (ethnographic, observations), semiotic or language studies (focusing on language and symbolism), and quantitative studies. Often organizational studies involve a combination of both qualitative and quantitative techniques mentioned above.^[9] Several methods are often needed when the aim is to study company values, practices, artifacts, and core tasks, finding underlying assumptions existing in the company.^[39]

ORGANIZATIONAL CULTURE IN THE LIBRARY CONTEXT

Organizational culture has also become important when studying libraries and how they can meet challenges and changes in today's society. Challenges in libraries are anchored in the demands that the information society shapes where especially the technical development has been of critical importance.^[40] The main goal for a library is to bring clarity into the information chaos and help the information users to find and use relevant information at the right time and place. Apart from the traditional information resources management issues there are aspects of user orientation which have also become important for libraries to manage. Collaborative and information sharing skills are highlighted. For example, sharing knowledge is important where librarians share desk duty and consistent

service is required.^[41] There is a growing trend of using libraries both locally and virtually giving them great potential for collecting new forms of user-produced information. The libraries need to reconstruct their role from being a physical location of information and knowledge, where the information professionals have all the keys to knowledge organization, to an organization where the users actively can take part in shaping the library and their information provision. The development of new electronic services, digital libraries, and new learning environments affect the structures and organizational culture within the library, and put great demands on their management.^[42-46]

Cultural studies in library organizations are challenging. As public organizations the libraries are different from, e.g., private as far as their external environment and expectations are concerned. Public organizations are often more structured and rule-oriented. This often means that public organizations are not often accustomed to change management or aware of the role of organizational culture in practice.^[47] The role of organizational culture in the context of change management has been underlined in some empirical library studies.^[42,48] Cultural studies in the library context have also discussed different organizational challenges for different kinds of libraries, e.g., the importance of a cross-cultural approach in the leadership of university libraries which are situated in large organizations with a variety of subcultures.^[49] Promoting cultural change and cultural awareness through training and leading by example has been showed to be effective when it comes to public organizations^[47] and is probably true in library context as well.

CONCLUSIONS

It has been stated that organizational culture is a multi-dimensional concept with many meanings and definitions. We have seen that culture is significant for how the organization functions, what is valued, what it is aiming for, how the aims are reached, and how capable the organization is to change. How people's knowledge is created, interacted with, and used is crucial in this process (p. 2).^[2] The company culture plays an important role in the company's ability to handle changes (e.g., new information technology), but also on a broader perspective, i.e., in the handling of information as a resource.^[50,51] Although the whole company culture is difficult to picture, it provides an easier way to analyze the information culture in order to focus on the role of information as a resource. Studying information culture is concluded to be a useful where aspects of organizational culture and IM are combined. In these studies the understanding of networks, motives for sharing, and learning aspects are important.^[52] IM and KM is about structure and management of information in organizations in order to shape better circumstances for organizational activities (p. ix).^[53] Today, most organizations are a mix of

traditional, digital, local, and global arenas making the information activities a great challenge. Naturally, these circumstances are shaped by environmental and cultural factors and IM should be adjusted to both internal and external specialties.

Studies into organizational culture today emphasize the individuals in a social context focusing on aspects of learning and knowledge creation. This is important while organizations in general and libraries in particular, face challenges in their organizational structures because of the technical development as well as the virtual and digital development, resulting in new tasks and services. The organization is not solely a physical entity which gives new perspectives on cultural issues in the organization. It is important to address these kinds of studies in the future.

Abstract

Organizational learning (OL) is a growing field that studies the processes through which new knowledge is learned and used in an organization. OL involves the leveraging of organizational knowledge assets and the continued development of an organization's knowledge base. While OL has been studied since the mid-1960s, there are many aspects of the field for which researchers have yet to reach a consensus. Most notable is the lack of commonly accepted definition of OL. Additional aspects that remain unresolved include the appropriate theoretical perspective from which to view OL and the identification of the most appropriate agent of learning. This entry begins with a discussion of the various definitions of OL followed by a brief history that highlights key OL researchers and key OL journals. The following section reviews cognitive, behavioral, and social constructivist perspectives of OL; the individual, group, and organizational levels as agents of learning; the commonly accepted components of the OL process; and the types of learning that occur in organizations. This entry concludes with a discussion of the value of OL and a map of the conceptual landscape of OL research.

INTRODUCTION

Organizational learning (OL) is an evolving field that studies the processes through which new knowledge is learned and used in an organization. OL involves the leveraging of organizational knowledge assets and the continued development of an organization's knowledge base.^[1–3] Knowledge assets can be viewed as the inputs, outputs, and moderating factors that are involved in the knowledge creating process, the sum of which forms the organization's knowledge base. While OL has been studied since the mid-1960s, there are many aspects of the field for which researchers have yet to reach a consensus.^[4] Most notable is the lack of a commonly accepted definition of OL. Additional aspects that remain unresolved include an appropriate theoretical perspective from which to view OL as well as which elements of the organization are the learning agents.

This entry begins with a discussion of the various definitions of OL. This section is followed by a brief history that overviews some key individuals in the field and the leading journals that publish OL research. The following section reviews cognitive, behavioral, and social constructivist perspectives of OL; the individual, group, and organizational levels as agents of learning; the commonly accepted components of the OL process; and the types of learning that occur in organizations. This entry concludes with a discussion of the value of OL and a map of the conceptual landscape of OL research.

DEFINING OL

While the field of OL has already received numerous and extensive reviews, there remains multiple conceptualizations and inconsistencies in the terminologies used to define OL.^[5] Distinguishing OL from other processes such as knowledge sharing, knowledge transfer, change management, and the learning organization, which are each sometimes confused with OL, is an appropriate first step in defining it.

The scope of OL extends beyond the processes of knowledge sharing and knowledge transfer to include processes through which new knowledge is understood, remembered, and embedded in the organizational level in a way that it can be easily reused in the future.^[6] In addition, OL is a continuous ongoing dynamic process, as opposed to a specific episode of organizational change, that focuses on managing ongoing collective learning processes. While on the surface the cognitive and/or behavioral changes that result from OL may appear to be punctuated or disjointed episodes of change, they are actually the result of fluid and continuous underlying OL processes.^[7] In this way, OL differs from traditional change management initiatives, which are generally conceived of as a process of various stages of freezing, changing, and refreezing.^[8]

Last, the two terms OL and the “learning organization” (a concept that was popularized by Peter Senge's 1990 book *The Fifth Discipline*) are often used interchangeably.^[9,10] However, the two domains focus on different research goals. Research on the *learning organization*

focuses on prescriptive and practice-oriented theory building that deals with specific applications of best practices that an organization *should* follow in order to become an organization that learns. In essence, the *learning organization* domain tries to identify *what* characterizes organizations that learn effectively and productively. This differs from the descriptive theories of OL which focus on describing the processes through which learning occurs in an organization.^[11,12]

When looking at explicit definitions of OL, one sees that the field is still saturated with an array of partially overlapping and sometimes contrasting definitions. Below are a few sample definitions:

...the ability of the institution as a whole to discover errors and correct them, and to change the organization's knowledge base and values so as to generate new problem-solving skills and new capacity for action. Organizational learning refers specifically to a change in organizational knowledge and values.^[13]

process in the organization through which members of the dominant coalition develop, over time, the ability to discover when organizational changes are required and what changes can be undertaken which they believe will succeed.^[14]

the process of improving action through better knowledge and understanding.^[15]

the acquiring, sustaining, or changing of subjective meanings through the artifactual vehicles of their expression and transmission and the collective actions of the group.^[16]

a dynamic process, occurring over time and across levels, that involves a tension between new and existing learning.^[7]

organizational learning as the process of change in thought and action—both individual and shared—embedded in and affected by the institutions of the organization.^[5]

A thorough review of these and other definitions of OL reveals a number of common themes:

Organizational learning is

- a cyclical process;
- a response to changes in an organization's environment;
- based on experience and observation;

that involves

- knowledge acquisition and distribution;
- collective interpretation and sensemaking;

and results in

- cognitive and/or behavioural changes;
- increased understanding of action–outcome relationships; and
- the embedding of new routines and/or practices.^[7,13,14,17–19]

Based on these common themes, an overarching definition of OL can be provided as follows:

Organizational learning is a process through which knowledge is developed and shared, changes in cognition and/or behaviour occur, and new routines and practices are embedded in the organization.

HISTORY

Early research on OL was initiated in the late 1950s and early 1960s by March and Simon, and Cyert and March respectively.^[19,20] Together with researchers such as Argyris and Schön,^[21] Levitt and March,^[22] Simon^[23] and Huber,^[24] these early OL researchers focused specifically on either the cognitive or behavioral aspects of OL. Until the 1990s much of the literature used the metaphor of knowledge acquisition to understand the process of OL.^[21–24] This metaphor suggested that learning in an organization was a process of employees acquiring new knowledge (cognition) and then acting upon it (behavioral).^[25] Research that has followed the knowledge acquisition metaphor has typically focused on the individual, who is separate from the organization, as the agent of learning.^[26]

Beginning in the 1990s, authors such as Brown and Duguid,^[27] Lave and Wenger,^[28] Cook and Yanow^[16] and Gherardi and Nicolini,^[29] began exploring a more participatory perspective in which learning was viewed as a social process.^[16,25,27–29] Within this social perspective, authors began to integrate individual learning with learning processes on the group, organizational, and interorganizational levels of analysis.^[26]

The literature on OL has grown considerably since the 1990s with notable increases in the new millennium. The growth of interest in OL has been attributed to the emergence of the knowledge economy in which knowledge, knowledge management, and OL are cited as key factors in creating and sustaining competitive advantage.^[4,30] Academically, journals such as *Management Learning* and *The Learning Organization* focus specifically on OL and the learning organization (with crossover between the two). Other popular journals for OL research include *Academy of Management Journal*, *Academy of Management Review*, *Administrative Science Quarterly*, *Human Relations*, *Management Science*, *Organization Science*, *Organization Studies*, *Sloan Management Review*, and *Strategic Management Journal*.^[31]

THEORETICAL FOUNDATIONS

Organizational learning has been explored from a number of theoretical foundations including the cognitive, behavioral, and social constructivist perspectives.

Cognitive

Cognitive perspectives of OL focus on changes in the mental states of the individual within the organization. These sorts of cognitive changes can manifest themselves as modifications to the individual's knowledge base, conceptual frameworks, mental models, beliefs, or interpretations and do not require any sort of behavioral change to qualify as learning.^[15,32] The organizational cognitive perspective incorporates the individual cognitive perspective, which emphasizes the ability of the individual to absorb and organize knowledge for later reuse, and extends this process in order to apply it at the level of the organization as a whole. The focus of inquiry in this approach is centered on individuals and the changes in their understanding of organizational knowledge.

Behavioral

Behavioral perspectives on OL view changes in an individual's observable behavior as a consequence of a stimulus-response occurrence. From this perspective, the internal cognitive processes of the individual are largely ignored, and it is the observable changes in behavior that are equated with learning. Behavioral theories of OL are based on three fundamental observations: 1) Organizational behaviors are based on routines where action reflects a sense of legitimacy rather than an understanding of action outcomes; 2) Routines are based on past experience more than on anticipation of the future environment. These routines include rules, procedures, strategies, belief, frameworks, culture etc. . . ; and 3) Organizations are target-oriented and behavior is based on success or failure in attaining specific targets.^[15] The focus of inquiry in this approach is thus centered on changes in routines which manifest as behavioral changes.

Social Constructivist

Finally, the social constructivist perspective examines the individual within the context of a social system and purports that people build their understanding of the world through constant sense making within their social systems.^[33] Consequently social constructivism moves away from strictly cognitive notions of information acquisition, storage, and retrieval as well as behavioral conceptions of change that are viewed as the simple consequence of stimuli and response. Instead, OL is viewed as a social process with multiple actors interacting within an organizational

environment. As individuals interact and converse, new knowledge is created and a shared social understanding of the world emerges. As people develop a common language and a shared knowledge base, organizational members begin to learn from their interactions with one another.^[34] Organizational theorists who favor this view emphasize the importance of relationships in creating and sustaining successful organizational practices.^[35] Consequently, the focus of inquiry shifts to studying learning in the context of organization-based social practices.^[36]

LEARNING AGENTS

One of the more controversial elements of OL is determining whether individuals, groups, or organizations are the agents of learning. Some of the literature suggests that only individuals are capable of learning and not the organizations as a whole. At the individual level of analysis, individual learning is said to lead to changes in beliefs, schemas, and behaviors in the organization. Others propose that learning occurs at the group level where the focus is on integrating knowledge from different parts of the organization. It is suggested that group learning leads to shared beliefs and concerted actions. A third group proposes that OL at occurs the organizational level, where learning is a process of institutionalizing knowledge and routines that have been learned.^[7]

Individuals

Individuals may be studied as the main agent of OL from both the cognitive and behavioral perspectives. Within the cognitive perspective, there are two main schools of thought about individuals as the agents of learning. The first views OL as a particular kind of individual learning that is simply occurring in an organizational context. The second suggest that it is possible to use individual learning theories to understand OL based on the similar capacities and capabilities that exist between individuals and organizations.^[4] In contrast, the behavioral perspective views changes in individual behavior as the mechanism that permits the organization to learn.

Numerous authors however, have found weaknesses with viewing the individual as the main agent of OL.^[4,16] Their arguments suggest that OL can not be studied by looking exclusively at individual learning because there is no evidence to suggest that an organization can learn through the same cognitive processes as individuals do. Others argue that focusing on individual behavioral responses fails to sufficiently take into account the social aspects of learning that are so critical to OL. Argyris and Schön argued that individual learning is a necessary but insufficient condition for OL.^[21] While individuals are undoubtedly agents of learning in organizations, OL is not just the cumulative result of individual learning events

repeated or captured on a larger scale. Many authors^[6,13,17,37] argue that individuals' learning processes and behaviors cannot be used as an appropriate metaphor for the processes that permit OL^[6,13,17,37] because the storage of and access to knowledge in the individual and the organization differ in dramatic ways. Individuals have access to personal knowledge that is rarely, if ever, accessible to organizations, while organizations can retain knowledge that has been forgotten or lost to individuals.^[13,38] Similarly, OL is not simply the sum of individual learning because behaviour at the collective and organizational levels is often significantly different from those of the individuals in an organization.^[13,23,37,38] Mob mentality or "group think" are examples of how collectives and groups of individuals can act in a manner that differs radically from how individuals might act on their own.

As these reviewed shortcomings emerged in the research field, many theorists began to look for a more appropriate agent of OL.

Groups

Social constructivism focuses on groups as the agent of learning in organizations. From a group level perspective, it is suggested that group learning leads to the development of shared beliefs and concerted actions which then results in OL.^[6,7] Organizational groups which may consist of such groups as formal teams, departmental divisions, or informal gatherings of colleagues who share similar professional interests, are viewed as the agent of OL from the social constructivist perspective. This latter type of group is generally referred to as "communities of practice" and are often perceived as the bridge between individual and OL.^[28,34] From a group level perspective, it is suggested that group learning leads to the development of shared beliefs and concerted actions which then results in OL.^[6,7] The emphasis in this perspective shifts from individual knowing, to collectively made decisions and agreements. The sensemaking processes that are critical to learning are no longer attributed solely to the individual but are recognized as fundamentally social in nature.^[34] The researchers who focus on groups as the agents of learning in OL view OL as a social process that constructs and situates knowledge within work practices.

For some authors though, even the group level perspective is insufficient for understanding how learning occurs in the organization.

Organizational

More recently there appears to be an evolution in OL research towards viewing OL as a process that occurs on all three levels of an organization (individual, group, and organizational).^[31] This view argues that learning at the organizational level is a process that can only occur once knowledge at the individual and group levels have been

collectively recognized, accepted, and used as organizational knowledge. Learning is thought to begin with individuals' cognitive and behavioral changes, followed by socially constructed interpretations of these changes and ultimately maintained by organizational adoption.^[39] At the organizational level, learning is embedded in the organization's systems, structures, procedures, and strategies which are then available to all employees on an ongoing basis,^[40,41] through a process that is referred to as "institutionalization" by Crossan, Lane, and White.^[7]

ORGANIZATIONAL LEARNING PROCESSES

A tension exists between learning by exploring new possibilities and learning by exploiting known certainties. Exploration involves searching for new information, experimenting, playing, taking chances, discovering, and innovating. It is a process that helps overcome organizational inertia and institutional rituals but that can be confronted with internal political resistance.^[42] Exploitation, on the other hand, involves refining existing knowledge, improving upon practices and procedures, and increasing efficiency. Exploration feeds new knowledge into the organization's knowledge base and exploitation feeds existing knowledge from the organization's core back to the individuals and groups who make daily use of it.^[43] OL cycles are affected by a trade-off between exploration and exploitation as the organization attempts to address both short- and long-term goals.^[44,45] There are a number of models that map out the various processes of OL which suggests that, while there is no single definitive model of OL processes, an underlying understanding of the processes is emerging.^[7,35,46,47] The following section provides an integration of these various models by adopting the terminology developed by Crossan, Lane, and White^[7] to describe four main OL processes: intuition, interpretation, integration, and institutionalization.

Intuition

Organizational learning is triggered by intuition. Intuition occurs when individuals identify and acquire knowledge that has potential use in their current work environment through pattern recognition (exploitation), or through making novel connections and identifying new possibilities (exploration) in the way they do their job. In many ways, intuition is seen as a preconscious process, in that the knowledge is hard to describe in concrete terms and often occurs as a result of observation, participation, or socialization.^[7,46]

Interpretation

Interpretation is the process through which individuals verbalize or put into action their own intuitions. It is also

the phase in which individuals develop personal cognitive maps of their knowledge. Metaphors, which describe a relatively unknown or unfamiliar domain in more familiar terms, are often used to help individuals interpret and share their insights and ideas with others. Finding the right words to describe intuitions is a critical part of the interpretation process. Interpretation involves individuals interacting with other organizational members in an effort to make sense of their own intuitions. Viewed in this way, interpretation can be seen as a social process that involves sensemaking activities between organizational members. At this stage, however, the process is still focused on making sense of the individual's ideas. Other authors have also used the terms exchange, distribution, or externalization to describe this process.^[7,24,35,46,47]

Integration

As the understanding and value of the knowledge extends beyond the individual and is shared among group members, the process is said to be one of integration. Integration involves the collective development of a shared understanding of new ideas and of how to put them into action. This process occurs and has impacts on the group level in the organization. Through continued conversations, group members engage in mutually adjusting each other's understanding of new knowledge and through this, an agreed upon way of making use of the knowledge emerges. This new knowledge can impact how the group works in ways that are often different than those prescribed in the organization's standard operating procedures, rules, or guidelines.

This process has also been called combination, which is a process in which new knowledge is combined with existing knowledge; and objectification, which is the process in which knowledge becomes common property and is accepted as being reliable, valuable, and useful by the organization's members.^[7,35,46,47]

Institutionalization

Institutionalization involves a deliberate effort to embed knowledge at the organizational level so that it may persist and be available for future use. This new knowledge then becomes a norm or custom of the organization and can at that point, be viewed as having been added to the organizational knowledge base. It is through institutionalization that individual and group learning is leveraged and capitalized on in an organization.^[7] In essence,

institutionalization is the process through which knowledge that has been intuited by individuals, and interpreted and integrated on a group level, is finally internalized into the organization's systems, routines, structures, and culture and consequently, can be seen as evidence of OL. Transfield and Smith explained that "this embedding, or institutionalizing of new ways of working, is complete when old tacit routines are removed and replaced with new taken-for-granted ways of working".^[48] Institutionalization is the process that distinguishes OL from individual and group learning as it is through institutionalization that ideas are transformed into institutions of the organization, which are then available to all employees on an ongoing basis.^[40,47] Fig. 1 shows how these four processes of OL occur at the individual, group, and organizational levels.

These processes are affected by internal politics and the organization's culture. In order to take into account the political nature of organizations, some authors^[40,42] have explored the influence that power has on OL processes. It has been argued that new ideas only have the opportunity to become institutionalized when they are championed by key players in the organization and when coalitions are formed to support the interpretation and continued development of the ideas. These can be seen as political activities in that champions will only support particular ideas at particular moments in time and coalitions will be instrumental in gaining resource allocation.^[42] These champions and coalitions are also instrumental in the institutionalization of new knowledge by using their power to get senior management and the rest of the organization in line with the new knowledge. Power may be used to influence people to accept a chosen interpretation, to drive particular ideas to the top of the organizational agenda, to restrict alternate options, and to socialize and train organizational members into the new way of thinking or behaving.^[40]

While these processes and the role of politics give the impression that OL is a particularly structured process, it is also appropriate to see it as a fluid and dynamic process that is greatly influenced by the organization's culture, identity, and ability to be self-reflective. An organization's culture, which includes its beliefs, values, and philosophies along with the artifacts and means through which they are transmitted across the organization, influences the way knowledge is interpreted, who will champion it, and when it can be integrated and institutionalized in the organization.^[16,49] Organizations with rigid cultures struggle in the exploration phase of learning because they cannot see beyond their existing organizational configuration, or

	Individual	Group	Organizational	
Individual	Intuiting	Interpreting		
Group			Integrating	
Organizational				Institutionalizing

Fig. 1 4I framework of organizational learning.
Source: Adapted from Crossan et al.^[7]

organizational identity, to envision ways to integrate new knowledge.^[50] To overcome such challenges, organizations need to be more actively reflexive and engage in improvisational learning and working. Improvisation has been used as a technique to support OL as it teaches the organization to quickly and dynamically interpret and process vague and incomplete information and to recombine past knowledge and experiences to create new solutions and directions for action.^[49,51] Schön^[52] refers to the activity of reflecting on past knowledge while acting as “reflection-in-action”. As organizations embrace these learning behaviors, their capacity to identify new potential strategic directions, to engage in transformative learning, and to adapt their organizational culture and identity increases.^[50]

TYPES OF OL

The processes of OL can be further characterized by three types of learning; single loop, double loop, and deutero-learning.^[21]

Single-Loop Learning

Single-loop learning involves the detection and correction of errors in routine actions. When single-loop learning occurs, the actions and rules of the organization may change, but the values and norms behind the actions are not questioned.^[53] In this type of OL, the focus is on improving specific techniques, routines, or work processes. New ways of carrying out routines can reach the organizational level (become institutionalized) without requiring any changes in organizational strategies, culture, or identity.

Double-Loop Learning

Double-loop learning occurs when the underlying causes of errors or poor performance are analyzed and altered.^[54] The focus in this type of learning is on the adjustment of cultural values, norms, and strategies rather than specific activities and behaviors. Resulting changes in routines are thus based on new organizational goals and perspectives.^[53] The results of double-loop learning may include the development of new organizational skills, cognitive frameworks, interpretive schemes and the unlearning of earlier, ineffective behaviors.^[15]

Deutero-Learning

Deutero-learning is a “meta” process in which the learner reflects on his own learning (either single- or double-loop learning). From an organizational standpoint this involves reflecting on the way the organization thinks about and approaches learning opportunities. This type of learning

can have an influence on the learning processes and culture that is already in place in an organization. Deutero-learning is actually less knowledge and skill dependent than double-loop learning as it can be a simple reflection on single-loop issues.^[53]

VALUE OF OL

Organizational learning is an essential activity for organizations in a knowledge-based economy. The strategic management of OL and knowledge assets is most successful when these activities are linked to the organization’s strategies, goals, and practices.^[55,56] When organizations focus their learning on strategic issues, these issues will influence the firm’s perception and interpretation of knowledge and this knowledge will in turn influence, and often renew, the organization’s strategies, goals, and practices.^[5] When learning is effectuated on the organizational level, the basic assumptions underlying organizational knowledge are reframed and can lead to changes in the strategic orientation of the organization.^[57] Linking OL with strategic goals helps build the organization’s ability to both discover new knowledge (exploration) and make the most out of the knowledge that it already has (exploitation).^[5,56]

Organizational learning is also at the heart of an organization’s ability to adapt and respond to a changing environment and can ultimately lead to improved business performance. Research has found that OL can enhance the survival and effectiveness of acquisitions, increase innovation, and facilitate the implementation of new information systems and business process reengineering.^[31] OL has also been shown to reduce costs and to contribute to organizational success by reducing the number of repeated tasks and preventing individuals from repeating the mistakes of others.^[58–60]

Organizational learning also contributes to sustainable competitive advantage by enabling organizations to learn faster and to deploy their knowledge assets more quickly than their competitors.^[2] Furthermore, an organization’s core competencies are typically the result of its collective and continuous learning and the ability to manage the knowledge assets that result from this learning.^[2,61] Managing these processes and assets allow organizations to achieve greater flexibility and adaptability, and through that, increased competitive advantage.^[17]

CONCLUSION

Organizational learning is a complex process that involves multiple learning agents, subprocesses, and types of learning and can be viewed from a variety of theoretical perspectives. The growing tendency in OL research is to integrate as many of these components as possible into a

Fig. 2 A conceptual landscape of organizational learning.

single framework. This implies integrating cognitive, behavioral, and social perspectives on learning to develop comprehensive models that explore the OL process as a cycle that affects, and functions differently, on all levels of the organizations. The following diagram (Fig. 2) represents a mapping of this conceptual OL landscape, highlights components that are critical for a more in-depth understanding of OL and can serve as a foundation for further research and exploration in this area.

An improved understanding of these key aspects of OL is crucial for more effective strategic management of learning at the organizational level.

Organizational Memory

Maureen L. Hammer

Knowledge Management, Batelle Memorial Institute, Charlottesville, Virginia, U.S.A.

Abstract

Organizational memory (OM) has to do with an organization's ability to access and use the knowledge, expertise, and experience gained by its staff for the purpose of meeting its ongoing business needs. Across the literature, there is consensus that the primary repository of OM is the staff that carries out the work of that organization. This is increasingly important given the large wave of retirements expected across the private and public sectors in the near future as well as a change in employment tenure as workers increasingly change jobs every 3–5 year. This entry provides a high-level review of OM.

How can an organization remember? what does that mean? and why should we care? Organizational memory (OM) is about the accrual and preservation of knowledge held and shared by its employees paired with the organization's history and culture. Together, these contribute to its uniqueness, all of which leads to competitiveness and improved decision-making. Evidence of it may also be found in the organization's documents, systems, and processes. OM may be lost through resignations, retirements, and reorganizations, as well as through deliberate or unconscious suppression. Memory loss can be expensive as without the benefit of prior knowledge and experience, organizations may duplicate work and have to relearn lessons.^[1] This entry provides a high-level review of OM. References at the end of this entry can be consulted by the reader wanting more detail or to further explore specific issues raised in the text.

As long ago as 1959, Penrose, in *The Theory of the Growth of the Firm*, recognized that an organization functions as a knowledge repository (as cited in Bontis).^[2] What goes into the repository is the tacit (unwritten and uncaptured) knowledge of its employees. Tacit knowledge influences the attitudes of individuals and is a knowing that informs the individual about how to best accomplish a task; it is produced by the individual and changed by experience.^[3,4] The knowledge is dynamic and can change frequently and take on new meaning as a result of new experiences.^[5] It is impacted by the individual's personal way of interpreting it so the knowledge may be held and explained differently person to person. Memory is the application of this knowledge, impacted by further experience, and the sum of all employees' knowledge becomes the institution's OM.

This knowledge must be passed on to each generation to establish continuity and to allow each generation to contribute to and build upon the previous knowledge base so that it becomes an organizational asset.^[6] Knowledge is further expanded and shared by the

relationships in which employees participate (their networks), by use of explicit knowledge such as databases and paper files, and through organizational processes and procedures that have been refined through lessons learned.^[7] Employees contribute to the dissemination of personal and organizational tacit knowledge; this is important because it ensures that the various interpretations can be heard, understood, and combined with the individual interpretations to build expertise. "From very early times, wise people have secured sustained succession by transferring in-depth knowledge to the next generation."^[8]

Kransdorff and Williams break OM down into three time frames, short term (less than 5 year), medium term (up to 10 year), and long term (over 10 year).^[1] It is the short- and medium-term memory that is most relevant to an organization's daily or core operations, while long-term memory impacts its strategy. Since OM is critical to an organization's ability to perform effectively (do the right thing) and efficiently (do things well) and much of this critical knowledge is held by individuals within the organization in tacit form, it is particularly at risk for loss in countries or sectors expecting a large number of long-term employees to retire. It is also increasingly impacted by the new trend of employees' tenure lasting five or less years and by outsourcing.

ORGANIZATIONAL MEMORY: DEFINITION AND OVERVIEW

In 2000, Olivera defined OM as the means of storing knowledge for future use by discussing OM as it relates to the complex environment of an organization that exists as multiple units and including networks of individuals, sophisticated computer-based technologies, and formal knowledge management initiatives. He discusses OM in

this environment as dispersed among people and documents and integrated through mechanisms such as social networks and computer-based technologies.^[9]

As important as individuals may be in creating the knowledge base, OM is more than just the addition of what individuals know or store in databases. The existence of an OM is what makes it possible for an organization to have a memory that is sustained even as individuals leave.^[10] It is through sharing by individuals, according to Walsh and Ungson, that “organizational interpretation is made possible” and “through this process of sharing, the organizational interpretation system in part transcends the individual level. This is why an organization may preserve knowledge of the past even when key organizational members leave.”^[11] Walsh and Ungson identify five storage bins for OM: individuals, culture, transformations, structures, and ecology, and one external bin—external archives.^[12]

Beazley, Beazley, and Harden identify seven types of operational knowledge:^[6]

- *Cognitive knowledge*: Content knowledge that includes job-specific data and information and their sources.
- *Skills knowledge*: The skills and training necessary to perform well in the position.
- *Systems knowledge*: An understanding of the interplay of cause-and-effect relationships that is essential for sound decision-making.
- *Social network knowledge*: An understanding of the crucial social relationships that make it possible to get things done in the organization, including who can grease the wheels, provide inside information, clarify options, or offer reliable advice and counsel. When employees face an unfamiliar situation with which they feel unprepared to deal, they do not rely on databases or procedure manuals. They turn to their network of trusted colleagues for information, knowledge, and advice.
- *Process and procedural knowledge*: Knowledge of formal and informal organizational processes and procedures, which are often more effective for getting things done in an organization.
- *Heuristic knowledge*: Knowledge of shortcuts for accomplishing tasks, rules of thumb for decision-making, and quick fixes that have come to constitute best practices for the position. Heuristic knowledge includes procedures that modify or circumvent obsolete, ineffective, or cumbersome official procedures.
- *Cultural knowledge*: Knowledge of organizational norms, values, roles, and standards of conduct that govern interaction with colleagues and other stakeholders.

The importance of OM to an organization lies in its role in problem-solving, decision-making, strategic planning, and developing tactical approaches. In 2006, Feldman and

Feldman note that “despite continued efforts to dismantle the concept’s mystery, it has not lost its essentially baffling quality.” They suggest that this baffling quality may be due to an approach that is too “narrow to capture the complex character . . . of organizational remembering.” They suggest a shift from the term “‘organizational memory’ (an object) to ‘organizational remembering’ (a practice)” and discuss organizational remembering as “a collective, culture and time specific process and practice, hinged on the concept of tradition as the cradling framework of meaning.”^[13]

ORGANIZATIONAL MEMORY AND CULTURE

“Culture embodies past experience that can be useful for dealing with the future. It is, therefore, one of organizational memory’s retention facilities. . . . Because this information is transmitted over and over again, some of the detail and context of the various decisions are likely to be dropped or even altered to suit the telling.”^[14]

According to Adler, Goldoftas, and Levine, management’s task is to create an environment that promotes interaction between the individual and the organization to share knowledge.^[15] “Managers must accept the inevitability of employee turnover, and through an understanding of social networks, make structural changes to their organization which promotes the diffusion of knowledge before crucial information is lost.”^[16] Brief and Motowidlo state that leadership style and organizational climate affect prosocial organizational behavior.^[17] Prosocial behavior supports knowledge sharing through encouraging interactions between employees. Leaders determine what activities are rewarded by role modeling and supporting wanted behavior such as networking. “Leaders have direct control over what activities are rewarded, what behaviors are encouraged, and how work will be valued in the organization. These factors all influence workers’ motivation and ability to develop new knowledge.”^[18]

A knowledge sharing culture is one in which employees are encouraged to share and to ask questions, where experience and knowledge from other sources are included, and where mentoring is supported.^[19] Awareness of and support for knowledge sharing networks and the individuals within is a critical function of leadership and management as the networks are used daily in the completion of work. “The traditional organization chart may show who reports to whom, but often who talks to whom is more important in getting work done and generating new ideas.”^[20]

Fahey and Prusak note that when management recognizes that knowledge is part of a process rather than an object, it will be recognized that it is affected by the organization’s structure and systems.^[21] Often knowledge sharing is confined to small groups of employees who

have developed a trusting relationship over the years. “A great deal of knowledge in an organization is undocumented and therefore isn’t easily available to everyone. It may be shared among a few individuals or within local groups, but rarely migrates outside those circles.”^[22] Organizational leaders and managers must create a culture that encourages sharing to these groups and beyond.

According to Choi and Lee, organizational knowledge management programs with a human orientation focus on the sharing of tacit knowledge. The human orientation is important in industries with high uncertainty or complexity because employees rely on the experience and knowledge within networking relationships.^[23] It is also valuable within more stable environments to ensure that organizations continue to grow and innovate. The human orientation can be complemented by a technical orientation that captures the supporting explicit knowledge and makes it available through a knowledge repository such as a searchable database or a corporate intranet.

TOOLS AND APPROACHES TO PRESERVE ORGANIZATIONAL MEMORY

“Devising strategies to properly manage knowledge is imperative for many organizations due to its significance for attaining organizational outcomes.”^[24] In addition to being stored in people’s memory or in databases, OM is embedded in processes, systems, services, and cultural norms. It is encoded in routines, in established policies and procedures, in products, in the way a business is organized, in the beliefs and routines in which employees are trained, and the cultural norms that guide how staff interact and share knowledge. And these things can, in turn, be impacted by “changing incentives, evaluation processes, or planning and budgeting processes.”^[25]

Knowledge sharing by individuals is fundamental to creating an organizational knowledge base—the foundation of OM. Walsh and Ungson note the important role of the individual in acquiring and sharing information. “This focus on individual cognitive activities as the central element in the organization’s acquisition of information reflects an active construction of memory.”^[11] It is in the give and take among individuals combining their understanding and experience of how to accomplish work (tacit knowledge) with known information (explicit knowledge) in a specific context that new knowledge is created.^[9,26–28] This creativity, in turn, allows an organization to more effectively exploit what it already knows if that new knowledge is transformed into organizational knowledge.^[29–31] This suggests that the process of learning by individuals and sharing of information by them is an important step in creating an organizational knowledge base.^[32,33] Networks among staff, in turn, are frequently identified as an important means of accumulating, accessing, and sharing knowledge.^[34]

As long-tenured staffs begin to leave, they take with them their knowledge, skills, and other valuable job-related information—components of the organization’s memory that may become inaccessible to the organization. Additionally, this loss may disrupt OM systems as these components are part of organizational knowledge that may be dispersed across actors, systems, and interactions in organizations.^[35]

Knowledge repositories—databases or document collections—are an important tool in storing and making accessible organizational knowledge, but they play a limited role. In practice, “people are about five times more likely to turn to friends or colleagues for answers than to other sources.”^[36] The U.S. Department of Defense identifies knowledge sharing as being 90% culture and 10% technology in its Knowledge Management Primer.^[37] Aside from usage tendencies, there are issues related to inputting information in such a way that it is accessible to users. A report by the U.S. Federal Highway Administration on a 12-state survey of Quality Assurance databases ended up concluding that “Data Rich and Information Poor” best describes the current status of today’s databases. The focus of many agencies is on entering data, not retrieving or analyzing the data.^[38] “Briefly, individuals store their organization’s memory in their own capacity to remember and articulate experience and in the cognitive orientations they employ to facilitate information processing. Moreover, individuals and organizations keep records and files as a memory aid.”^[39] Therefore, encouraging employees to share their knowledge and to capture elements that explain the “why” of actions and strategies in databases may act as a catalyst for remembering.

OM may be shared between members of a group for a specific purpose or it may be passed down through mentoring or apprenticeships.^[26] Tacit knowledge originates with the individual and it is necessary for that knowledge to transfer from person to person to be useful to the organization. One way of transferring is described by Nonaka and Takeuchi as socialization, the sharing of experience to create shared mental models as through apprenticeships.^[29] It might also be codified within organizational routines through rules and guidelines:^[2]

The organization, however, cannot dictate the rules of coordination and knowledge sharing. Since only a part of tacit knowledge is internalized by the organization, the other part is internalized by employees. Therefore, it becomes critical for management to find some kind of commonality between individual and organizational knowledge and provide necessary incentives to employees to share their knowledge and enhance the contents of the organizational knowledge base.^[40]

Sharing is dependent on the levels of solidarity and employee buy-in to organizational goals.^[41] Leadership is

critical to garnering this buy-in and willingness to share. Management is critical to establishing the means to share both explicit and tacit knowledge.

“Blue-collar skills are predicated on available explicit knowledge; white-collar skills are predicated mainly on the less-than-visible tacit experience. Explicit knowledge can be taught while tacit knowledge is best learned. . . . Teaching is instruction *received*. Learning is instruction *acquired* out of an abstracted process of critical reflection, reasoned deduction, and applied action, the evidential base for which is OM.”^[42] “Learning as an integral part of working occurs when individuals adapt new tools to solve current problems, share success and failure stories, etc. Unlike individuals who are ‘automatic’ learners, OL (Organizational Learning) is a conscious activity in the organizational context and can be enhanced by an effective knowledge-management system.”^[43] Individuals develop knowledge based on personal experience, their personal values and beliefs, and the addition of new knowledge, thus determining what it is they remember.^[13] Providing training and education will ensure the sharing of explicit knowledge. Creating networks, such as through communities of practice, will support sharing of tacit knowledge and provide access to those with expertise and experience.

Access to experts within the organization is important to problem-solving, building the knowledge base of employees and innovation in product construction or delivery. “The role of experts is important as they are ultimately the source of the innovations or knowledge that is being diffused. Consequently, they form local peaks in the knowledge distribution, and agents directly connected to them benefit, becoming second-order experts.”^[44] By sharing knowledge with others, the demand on the time of experts is lessened freeing the expert to focus on high-value projects. It also supports the redundancy of knowledge within the organization ensuring that knowledge does not walk out the door. Lesser and Prusak state that

The research and experience at the Institute for Knowledge Management has shown that social networks play a critical role in helping people identify, share and work with corporate knowledge. Through such networks, individuals identify experts, provide referrals for those seeking answers and facilitate knowledge transfer among groups. Downsizing disrupts the structures and causes ‘potholes’ that impede and often block the flow of knowledge.^[45]

The presence and support of networks within the organization supports knowledge sharing by creating opportunities for employees to exchange information and insight informally as well as formally. Access to different knowledge through interactions with others allows employees to update their knowledge banks.^[42] The transfer requires that members of the network share a common framework to effectively share knowledge.^[46] This can be accomplished through organizationally supported

communities of practice to share lessons learned and after-action reviews. According to Swan et al., “knowledge has to be continuously negotiated through interactive social networking processes.”^[47] It is the organization’s responsibility to establish a culture or environment that supports the forming of these networks, both loose and tight, to encourage the sharing of knowledge.^[26,47]

Networking with external experts is also critical. Many of these networks are based on personal relationships. Creating an expert database to share these relationships can be helpful to other employees. “External memories are accessed through directories held in the mind of individual team members that identify existence, location, and mechanisms for retrieval of knowledge held by other team members or in various storage devices.”^[48] These connections may be direct or indirect.

In the 1960s, an American psychologist named Stanley Milgram tried to form a picture of the web of interpersonal connections that link people into a community. To do so, he sent letters to a random selection of people living in Nebraska and Kansas, asking each of them to forward the letter to a stockbroker friend of his living in Boston, but he did not give them the address. To forward the letter, he asked them to send it only to someone they knew personally and who they thought might be socially ‘closer’ to the stockbroker. Most of the letters eventually made it to his friend in Boston. Far more startling, however, was how quickly they did so—not in hundreds of mailings but typically in just six or so. . . . Milgram’s findings became famous and passed into popular folklore in the phrase ‘six degrees of separation.’^[49]

Often, the size of the organization influences how easily and readily employees share information. The smaller the organization, the more likely employees will share as they know and trust each other.^[50,51] Sharing may also be affected by employee age and where they are in their career.^[50] Sveiby and Simons found that senior people are more experienced in sharing knowledge than junior people due to larger networks and that investing time in assisting less experienced employees to build these networks in the first 3–5 year of employment is a profitable investment by the organization.^[52] While this may not be practical now given the increasingly short tenure of employees, developing a mechanism to quickly acquaint them with expert networks will benefit the organization.

ORGANIZATIONAL FORGETTING

If organizations remember they also forget, either deliberately or through a lack of awareness of knowledge at risk because it has not been shared.

Organizations that have been deeply concerned about organizational ‘learning’ have been oddly negligent about

its opposite: corporate 'forgetting,' which occurs with every departing knowledge worker. What kind of organizational learning can take place if the knowledge base on which it relies is subject to continual degradation or if the organization itself cannot remember enough to pass on its knowledge and its secrets to the newcomer expected to carry the torch?^[53]

However, strategic forgetting is also important. According to Bontis, much of the literature fails to acknowledge that while tacit knowledge can contribute to the competitiveness of an organization it can also limit its competitiveness if that knowledge does not fit the context of the desired industry.^[2] At the same time, too much forgetting may impact employee ability to identify with the organization. Organizational forgetting may be by mistake or on purpose and it may be helpful or hurtful to the organization and therefore, organizations need to also pay attention to what and how they forget in a strategic way. Strategic forgetting may be employed to help employees learn and adapt to new circumstances. Non-purposeful forgetting may hurt the organization when it loses the value of lessons learned that might be helpful to future events. Official and personal historical memories can omit or neutralize events and perspectives that contradict the approved history. This may be purposeful or unintentional. The emphasis on remembering and on forgetting impacts the actual history.^[54]

It is necessary to strategically capture knowledge that the organization wishes to retain and embed it in procedures and the culture.^[55] If the organization forgets critical knowledge, it must be relearned or created anew at great expense and can affect the competitiveness of an organization.^[53] It can also be harmful as seen in the Challenger and Columbia disasters at the U.S. National Aeronautics and Space Administration where the focus was on the

Quantitative measure 'experience base.' (In 1986 the Space Shuttle Challenger broke apart 73 sec into its flight. In 2003, the Space Shuttle Columbia broke apart on reentry over Texas). This measure abbreviates memory to a dangerously low level because it not only excludes qualitative data, but also arrests and reifies memory by excluding historical analysis of quantitative data relevant to safety and other organizational goals. In other words, a lack of memory was not only responsible for misunderstanding the level of risk on Columbia's last flight, but engineers also did not notice the accumulation of risk in the flight history preceding Challenger.^[56]

Unfortunately, the organization may not be aware of its knowledge if it lacks awareness of employees' personal knowledge.

Managers do not know the value of their own intellectual capital. They do not know if they have the people, resources, or business processes in place to make a success of a new strategy. They do not understand what

know-how, management potential or creativity they have access to with their employees. Because they are devoid of such information, they are rightsizing, downsizing, and reengineering in a vacuum.^[57]

As employees leave, they take the organizational knowledge with them, employee networks are disrupted, and documentation is lost or hidden.^[58] According to Lesser and Prusak, when organizations downsize, it is often the most knowledgeable employees who leave first, resulting in a damaged critical social network and an increase in time needed for knowledge transfers.^[45] This often occurs when organizations offer buyouts and early retirement incentives without considering the knowledge held by those designated as eligible. These knowledgeable employees have built and maintained extensive networks used to share knowledge. Trends such as rightsizing and reorganizations along with the pending retirements of long-term employees and the mobility of the new workforce destroyed or compromised tacit knowledge networks. The informal contract between the company and an employee moved from employment for life to employment for as long as there is mutual benefit.^[59] As noted earlier, trust is a determining factor for knowledge sharing, and when organizations have a history of downsizing, trust is compromised and requires focused attention to reestablish.^[60,61]

CONCLUSIONS AND RECOMMENDATIONS

OM is the accumulation of employees' knowledge and experience. It is the means through which an organization ensures that its historical knowledge, experience, and expertise are retained to support its future. While snippets of it may be captured for future use in databases, processes, and procedures, the richness of the knowledge is only realized in ensuring employees are provided with opportunities to share and discuss their personal knowledge. Focusing just on structure, like databases and processes, means we miss the activity happening between people. Leadership is required to ensure focus on its importance to the organization and to create a culture that values knowledge sharing. Management is required to ensure opportunities for sharing and learning are supported. Careful consideration is required to determine what should be remembered and retained for consistency and competitiveness versus what should be strategically forgotten to allow room for innovation and adaptability. Failure to consider this strategically may result in inaccurate remembering or loss of cultural knowledge when employees leave.

By building up knowledge sharing networks among staff, organizations are not just able to share information, but it becomes second nature when there is a need. This conclusion is supported by a 2006 study by Scalzo looking at mid-sized financial services organizations with

approximately 2500 employees and that underwent radical change (a significant shift in values, behavior, and how the organization performs the work required to meet organizational need). Scalzo found that an organization can successfully manage the process in order to retain the wealth of information and knowledge that exists in the OM. The findings showed that the subject organization of this research study followed three key management practices throughout the entire change process (ongoing communications, senior management commitment, and planning) that enabled it to access, share, and retain its OM while undergoing radical change.^[62]

Pacific Islands Association of Libraries and Archives (PIALA)

Arlene Cohen

Pacific Islands Library Consultant, Seattle, Washington, U.S.A.

Abstract

The Pacific Islands Association of Libraries and Archives (PIALA) is a voluntary association established within the islands of Micronesia in the Western Pacific Ocean. Officially created in 1991, it has grown to be a stable association of librarians and archivists, holding annual conferences on different islands, supporting training opportunities, encouraging awareness and fostering resource sharing among libraries, archives, museums, and related institutions in the Pacific Islands.

INTRODUCTION

The Pacific Islands Association of Libraries and Archives (PIALA) is a regional association established in 1991 within the islands of Micronesia in the Western Pacific Ocean. The islands include the United States (US) Territory of Guam, and the former U.S. Trust Territory entities of the Commonwealth of the Northern Mariana Islands (CNMI); the Federated States of Micronesia (FSM) comprising the states of Chuuk, Kosrae, Pohnpei and Yap; the Republic of the Marshall Islands; and the Republic of Palau. The goals of PIALA are to promote knowledge of the functions, resources, services, and needs of regional collections of information resources; to develop and promote programs for the extension and improvement of information literacy and services in the region; and to provide an ongoing forum for people working in libraries, as well as archives and museums.

Regional Context

Micronesia, meaning “tiny islands,” is composed of some 2200 volcanic and coral islands spread throughout 4,500,000 mi² of the vast Pacific Ocean (see Fig. 1).

Lying north of Australia, south of Japan, east of the Philippines, and west of Hawaii, these tropical islands cover an expanse of water almost as large as the mainland United States, yet the total landmass is less than 1200 mi², with a total population estimated at no more than 300,000 inhabitants.

The region has a history of foreign involvement dating back to 1521 when Fernando Magellan, sailing for Spain, landed on the island of Guam. Throughout the next several hundreds of years, the Micronesian islands have been at various times under Spanish, German, Japanese, Australian, British, New Zealand, and United States rule. After World War II, with the exceptions of Guam, Kiribati, and Nauru, all the islands were designated by the United Nations as a Trust Territory to be administered by the

United States with the eventual goal of each achieving some type of self-government. Over the past 50 years, these U.S. affiliated islands have grouped together into five separate political entities (with one entity, the FSM, comprising four separate states). These political entities are reflected in the composition of PIALA. Although Kiribati and Nauru are geographically considered part of Micronesia, they were not included when establishing PIALA. Recently, representatives from the *Kiribati Library and Information Network (KLIN)*, the local Kiribati library association, have participated in PIALA conferences.

HISTORICAL BACKGROUND

The seeds for regional cooperation that grew into a regional association go back to the early days of the Trust Territory of the Pacific Islands administration and the work of Daniel Peacock, Director for Library Services for the Trust Territory. Through his efforts, Peacock established the foundation from which PIALA could emerge. In his insightful article, “Micronesian Library Services,” Nicholas Goetzfridt^[1] provides a context for understanding Micronesian library development and the significant role Peacock played in fostering this development.

In 1967, when the Trust Territory became eligible for the *Library Services and Construction Act (LSCA)* funds, Peacock wrote both the 1967, and later the 1972 state plans, providing funding for library projects in the region. Very early on, Peacock saw the need for regional networking and “The 1972 state plan called for increased bibliographic cooperation between the Trust Territory and ‘the libraries of the neighboring Pacific area.’”^[2] This is further discussed under the section “Resource Sharing” in this entry.

The 1978 *Commonwealth of the Northern Mariana Islands Pre-White House Governor’s Conference on Library and Information Services*, held on Saipan, was a first attempt to bring regional librarians together, although

Fig. 1 Map of the Pacific Area. Created by Joanne T. Crotts.

Source: From *Developing library and information services in Micronesia*, by A. Cohen, J.T. Crotts, I. Lovas, In *Libraries: Global Reach/Local Touch*, de la Pena Cook, K., Ford, B.J., Lippincott, K., Eds., American Library Association, Chicago, IL. 1998, 58. Revised for this entry by the author (Arlene Cohen) with permission of the creator.

no formal organization emerged from this gathering. Twelve years later, the 1990 *Commonwealth of the Northern Mariana Islands Pre-White House Governor's Conference on Library and Information Services*, held again in Saipan in October of that year, finally provided the impetus for the establishment of a regional association. Several participants and observers from outside CNMI were invited to attend and during the conference, an informal meeting was held to discuss establishing a regional library association. Minutes of the meeting were taken and the group called themselves the *Western Pacific Library and Archives Association*.

The 1990 *Guam Pre-White House Governor's Conference on Library and Information Services* was held the following month and the group met again informally in Guam. During this meeting, funding from the U.S. government was identified to hold an organizational meeting at the University of Guam in February 1991. With funding secured, two participants each from the Federated States of Micronesia, the Republic of Palau, the Republic of the Marshall Islands, the Commonwealth of the Northern Marianas Islands, and the Territory of Guam were invited to the organization meeting. At that meeting, a set of *By-Laws* was adopted, the Executive Board was elected and Palau was selected as the site of the first conference, planned for November 1991.

Soon after the organizational meeting, Margo Vitarelli, a prominent artist and educator in Micronesia designed the

letterhead of PIALA using Micronesian art motifs. Her design is still being used today, incorporated into the *PIALA Newsletter*, announcements, brochures, and other publications.

Thus, PIALA was born. From the onset, people working in museums have been an integral part of PIALA. In 1991, at the first PIALA general meeting in Palau, there was an attempt to change the name of the association to the *Pacific Islands Association of Libraries, Archives and Museums* (PIALAM); however, the attempt failed and the name has remained PIALA.

Throughout the years, several publications about PIALA have appeared, many of which are listed at the end of this entry. One article worth noting came about during Barbara J. Ford's term as President (1997–1998) of the American Library Association (ALA). Under her leadership, *Libraries: Global Reach/Local Touch* was published, and includes a detailed description of the development of PIALA in the chapter on library services in Micronesia.^[3]

In 1996, PIALA began submitting information to the Belgium-based *Union of International Organizations* (<http://www.uia.be/>), with updates submitted yearly.

As PIALA evolved, so did the materials documenting the association. Serving as a model for the importance of preserving historical materials, the permanent collection of PIALA archives was established and are housed in the Pacific Collection of the College of Micronesia—FSM

National Campus Learning Resources Center in Palikir, Pohnpei, Federated States of Micronesia.

GOVERNANCE

The *Pacific Islands Association of Libraries and Archives By-Laws* were adopted on February 28, 1991. Interestingly, the *PIALA Constitution* was not drafted until 1993, reflecting what was already in the *By-Laws*.

The original *By-Laws* included the purpose, duties of officers, composition of the Executive Board, voting, the committee structure, and dues. The group also decided that the venue of the annual meeting (including the annual conference) would rotate among all locations represented. By having the meetings on different islands, local librarians and archivists with little possibility to travel would have the opportunity to plan and attend a professional conference. Moreover, hosting a conference would also provide an excellent advocacy opportunity, focusing attention on the island's libraries, archives, and museums.

Purpose

The purpose of PIALA, as established in the *By-Laws* in Article II, Section A is

- a. to foster awareness and encourage cooperation and resource sharing among the libraries, archives, museums, and related institutions of the Pacific Islands;
- b. to promote knowledge of the functions, resources, services, and needs of regional collections;
- c. to develop and promote programs for the extension and improvement of library, archival, museum, and related services in the region;
- d. to improve a forum for discussing issues of interest to libraries, archives, museums and related institutions;
- e. to provide a vehicle for the exchange of ideas and information to librarians, archivists, museum curators and related personnel; and
- f. to offer continuing education experiences for library, archival, museum, and related personnel.^[4]

By-Law changes

Although the purpose of PIALA has not changed over the years; other parts of the *By-Laws* have changed to reflect the development and changing needs of PIALA.

When PIALA was established, the *By-Laws* stated that "The Executive Board shall consist of the officers, shall represent all locations, and have no fewer than five members. Locations not represented by officers shall elect a representative."^[5] Over time, the island states of Chuuk, Kosrae, Pohnpei, and Yap were considered locations in their own right and subsequently the *By-Laws* were changed to expand the Executive Board to no fewer than

nine members. Other important changes included dropping the office of Executive Secretary; allowing all members to vote, including institutional members, instead of just individual members; voting at the annual meeting instead of by mail; and accepting proxy votes. Attesting to the stability of PIALA's governance structure, the last time the *By-Laws* were changed was November 1996.

PIALA Board Meetings

Soon after PIALA was established, the Executive Board attempted, with varying degrees of success, to hold monthly meetings and this effort continues. The PEACESAT (Pan-Pacific Education and Communication Experiments by Satellite) federally funded satellite network has been used since the beginning and remains the most economical means of voice communication. PEACESAT stations are on the major Micronesian islands; however, the system has limited channels, tight schedules, and frequent breakdowns, with few spare parts available locally and limited local expertise to carry out the repairs.

In 2007, an attempt to conduct PIALA Board meetings using an online collaboration and conferencing system was tested. After several unsuccessful attempts to bring the group online, it was abandoned. It became clear that any new communication system, no matter how extensive the documentation is, must be accompanied by hands-on, onsite training for most users.

Happily, in the past few years with e-mail becoming more widely available and less costly, much of the work of the PIALA Executive Board is handled this way, with monthly scheduled PEACESAT meetings held whenever possible.

FINANCIAL ORGANIZATION

When PIALA was established, a bank account was set up in the Commonwealth of the Northern Mariana Islands. A few years later, this became the PIALA Publications account and another account was set up for general income and expenses. There is usually an account also set up on the island where the conference will be held, sometimes in conjunction with the establishment of the local library association. These arrangements have worked well throughout the years. However, with the retirement of the author from the University of Guam, the PIALA Publications account has been closed.

Although not part of the *By-Laws*, to facilitate the planning of the annual conference, PIALA provides \$500 as seed money to the island entity hosting the conference. Conference registration fees become part of the PIALA treasury, although any pre- or postconference fees remain with the hosting island.

MEMBERSHIP

PIALA members are divided into two categories: individual and institutional or corporate members. The membership fee was established with the founding of PIALA and to date, has never been increased. The fee for an individual member is \$20 per year, and institutional or corporate membership is \$50 per year.

Membership is not restricted to PIALA's geographical boundaries. In December 2007, PIALA had 63 currently paid members representing Micronesia, several other Pacific Islands and Hawaii. In the past, people have joined PIALA from Australia, New Zealand, the Philippines, Japan, Canada, Finland, Sweden, the United Kingdom, and the continental United States; however, it is difficult to collect membership fees on an ongoing basis. They are usually paid at the annual meeting. Many people from outside of Micronesia who have attended a PIALA Conference usually join at that time, but do not keep up their membership in succeeding years.

COMMUNICATIONS LINKS AND PUBLIC RELATIONS

Given the vast geographic area covered by PIALA, coupled with the reality of costly and unreliable telecommunication systems, one of the biggest challenges is maintaining membership and communication links within the PIALA and promoting the association throughout the world. PIALA uses several methods to communicate, as described below.

PIALA Newsletter

The *PIALA Newsletter* was born soon after PIALA was established, with the first issue published in June 1991. When first launched, it was hoped that the newsletter would be published quarterly. Although the publication has continued throughout the years, being a volunteer effort has made for an irregular publication pattern. All issues ever published appear on the PIALA WWW site (<http://piala.org.googlepages.com/newsletter>) (accessed September 2008).

As many parts of the world still have inadequate, costly, slow, and unreliable Internet access, paper copies of the *PIALA Newsletter* are mailed to all individuals and institutions that are or have been members in the recent past, or have participated in an annual conference. PIALA maintains a distribution list used for mailing the *PIALA Newsletter* throughout the region and the world. This has been an important way to keep people involved in the association, even if they may not have recently paid dues. As of October 2007, we had 393 addresses on our list. Although the last issue of the PIALA Newsletter was published in 2005, it is hoped future issues will appear.

PIALA Web page

The first PIALA Web page appeared in 1995 and was the result of the collaborative efforts of the author and Tom C. Gerhardt, an information scientist with an interest in the Pacific at Saarland University and State Library in Saarbrücken, Germany. The site was hosted on a server at Saarland University and remained there for several years. In 1998, the University of Guam offered to host the www page and it continued to reside on their server until early in 2008, when it was moved to (<http://piala.org.googlepages.com/>) (accessed September 2008).

PIALA Listserv

In 2000, an electronic mailing list for PIALA was established on the University of Guam Robert F. Kennedy Library server. A few years later, the list was moved to a server at the Secretariat of the Pacific Community in Noumea, New Caledonia, where it currently resides. This is an open list and anyone with an interest in PIALA or Pacific Island libraries, archives or museums may subscribe to it. As of the beginning of 2008, there were 132 subscribers and the number of messages posted varies between 15 and 50 per month. [Anyone with an interest in PIALA or the Pacific Islands can subscribe to the PIALA list at http://lists.spc.int/mailman/listinfo/piala_lists.spc.int (accessed September 2008). The PIALA list archives beginning from 2001 are available for public access at <http://lyris.spc.int/read/?forum=piala> (accessed September 2008). Archives beginning in August 2006 are also available at http://lists.spc.int/pipermail/piala_lists.spc.int/ (accessed September 2008).]

PIALA Proceedings

Beginning with the PIALA 1993 Conference held in Saipan, Commonwealth of the Northern Mariana Islands, the proceedings of most conferences have been published, with some exceptions. The PIALA 1999 Conference proceedings were never published, the PIALA 2001 Conference was cancelled, and the PIALA 2002 and PIALA 2003 Conference proceeding were not published as well. The PIALA 2004 and PIALA 2005 Conference proceedings were published as one volume, and the proceedings for the PIALA 2006 and PIALA 2007 Conferences are still in process.

Once published, the volume is submitted to ERIC (Educational Resources Information Center) in the United States and is available online in full text from the ERIC www site (<http://www.eric.ed.gov/>) (accessed September 2008), as well as the PIALA www page (<http://piala.org.googlepages.com/proceedings>) (accessed September 2008). They are also deposited with the United States Library of Congress and have ISBN numbers assigned.

One complimentary copy of each edition of the proceedings is deposited in every public and academic library throughout Micronesia. A complimentary copy is also given to each contributor included in the publication. They are also sold worldwide and the money received from the sale has been used to publish succeeding volumes. In the future, it appears that all new editions will be available only electronically, at no cost.

PIALA CONFERENCES

The traditional *bai* (a traditional Palauan men's hut or council house) on the grounds of the Belau National Museum was the venue of PIALA's first conference held in November 1991, with the theme *Preserving Knowledge for Tomorrow*. Over 40 participants from throughout Micronesia, Fiji, Hawaii, and the mainland United States gathered in the *bai* to hear presentations on resource sharing, preservation techniques for the tropics, serials and government documents, continuing education, and electronic telecommunications (see Fig. 2).

With each year, this eagerly awaited conference moves to another island with a new theme, and a continually growing number of local librarians and archivists participating and appearing on the conference program. Although the same general areas from the first gathering still are discussed, each year new topics are added to reflect the changing landscape of the field and new areas of interest.

A keynote speaker is selected for each conference. One memorable keynote speech was given by Norma Amenu-Kpodo, the Executive Secretary of the *Commonwealth Library Association*, coming all the way from the island of Jamaica for the PIALA 2000 Conference in Guam. She presented *Library Associations in Developing Countries: the Caribbean Islands as a Point of Comparison with*

Micronesia,^[6] conveying in her paper that no matter where in the world your library association resides, we all face an array of the same problems. At the PIALA 1995 Conference in Yap, Dr. Marcia Bates from the University of California at Los Angeles presented another important keynote speech, "*Learning About Your Users' Information Needs: A Key to Effective Service*."^[7]

In 1996, at the Marshall Islands PIALA Conference in Majuro, the first PIALA resolution was passed,^[8] addressing the need for cost-effective high performance Internet access to libraries and archives. In passing this resolution, the association took on an important advocacy role in fostering library development and information access in the region.

In addition to providing an opportunity to experience a professional conference for many who do not have the opportunity to travel, the PIALA conferences have served to promote libraries and library services to the host island communities. Local government officials are always invited to the opening session in hopes that they show their support for local libraries, and are encouraged to speak on behalf of their government, with their remarks being included in the *PIALA Proceedings*. Local newspapers usually report the event, along with local radio and television coverage. Usually banners announcing the conference appear at the airport to welcome participants and decorate the conference venue.

PIALA conferences are also used to exchange local resources. Local telephone books and college catalogs are among the most popular materials exchanged. There is also a time set aside for each island group to report on their activities during the year, providing for the exchange of new ideas between participants. Tours of local libraries, archives, and museums are always a part of the conference, providing local hosts the opportunity to proudly spotlight their facilities and for participants to become familiar with the islands' resources.

Fig. 2 Participants sitting in the Belau National Museum's traditional *bai* during a session at the first PIALA conference. Photograph by Arlene Cohen (the author).

Depending on the venue, the conference draws between 50 and 75 people, with about 40–50% of the participants representing the local island hosting the conference. Conference registration fees are usually determined by the local organizers, as well as pre- and postconference workshop fees. To promote the conference and raise local funds, PIALA T-shirts are usually sold during the conference.

Because conferences are planned by people on the hosting island, PIALA conferences have at times spurred the establishment or reawakening of local library associations. After PIALA met on Palau in 1991, the local librarians established the *Palau Library Association*. Soon after the 1992 conference, the Marshall Islands also established their own local library association. A library association was formed in Yap prior to the 1995 annual conference held there. Although Pohnpei has hosted PIALA Conferences from the beginning, it was in 2006 that the *Libraries, Archives, and Museums of Pohnpei (LAMP) Library Association* began to meet informally. The *By-Laws* and a charter are currently in draft form, almost ready to be formalized by the membership. Chuuk and Kosrae began working to revitalizing their library associations soon after the *Library Advocacy Workshop* held at the PIALA 2006 Conference in Palau. The *Guam Library Association* had been active for several years before PIALA was established and took an active part in the PIALA 1994 and PIALA 2000 Conferences held in Guam.

A *Chronology of PIALA Conferences* was published in the 2004/2005 *Proceedings*, including the conference theme, date, and conference venue.^[9]

ADVOCACY

As in many parts of the world, Pacific Islands government officials, educators, and the public generally do not appreciate the role and value of libraries in our society. Given this reality, library associations must take an active role in influencing government decisions in such areas as basic funding for libraries, new emerging areas of information literacy, copyright, indigenous knowledge, training, and telecommunications technology. However, to have any impact, library association leaders must understand the role of library associations as pressure groups for political action and policy decisions, and must have the requisite skills in policy development and implementation, building effective advocacy campaigns and public relations.

To address this advocacy training need, at the PIALA 1997 Conference in Pohnpei, a postconference workshop on library advocacy was presented by Tuula Haavisto, then the Finnish Library Association Director General. The workshop was funded by the *International Federation of Library Associations and Federations (IFLA) Advancement of Librarianship in the Third World Programme* and brought local librarians from throughout Micronesia to Pohnpei. At the PIALA 1998 Conference in Kosrae the

following year, several participants reported on their advocacy projects.

Several years later in 2005, another library advocacy workshop was proposed and funding was again obtained from the *IFLA Advancement of Librarianship in the Third World Programme*, as well as the *IFLA Management of Library Associations Section (MLAS)* and the ALA. At the PIALA 2006 Conference in Palau, the library advocacy workshop was held as a preconference and was presented by Keith Michael Fiels, the ALA Executive Director and Michael Dowling, the ALA International Relations Office Director.^[10] This workshop also brought library association leaders from throughout Micronesia, as well as Papua New Guinea and Kiribati.

At the Palau advocacy workshop, the participants prioritized issues ripe for advocacy, which reflect the pressing needs in the region. Those areas were

“Increased government funding for library materials and technology
Funding and resources for school libraries and librarians
Need for national libraries and archives
Extension of services for un-served regions and islands and
Increase public awareness of value and benefit of libraries.”^[11]

Participants created action plans for their islands and the following year, presented reports of their work at the PIALA 2007 Conference in Tinian. Most recently, stemming from the Palau advocacy workshop and the subsequent Tinian reports, Atarino Helieisar presented a paper on library advocacy in Micronesia at the 74th IFLA Conference in Quebec, Canada. <http://www.ifla.org/IV/ifla74/papers/093-Helieisar-en.pdf> (accessed September 2008).

Moreover, as a result of the advocacy training, several islands were able to obtain funding for projects, and local library associations in Chuuk, Yap, and Kosrae were refreshed.

Thanks to PIALA, librarians throughout the region are aware of each other's needs, issues, and challenges, and help to advocate for each other. Recently, a librarian from Guam worked to establish a school library in Kapingamarangi, an isolated atoll in the Federated States of Micronesia. In another instance, a terrible typhoon in 2004 completely devastated the Yap State Public Library and the Yap State Hospital Medical Library in the Federated States of Micronesia. The author of this entry, working with another Guam librarian wrote successful grants to help reestablish these libraries.

TRAINING INITIATIVES

The region faces a serious lack of professionally trained librarians, archivists, and museum curators. In a plea made

by Jean Thoulag, Vice-President for Institutional Affairs at the College of Micronesia—FSM at the PIALA 2005 Conference in Kosrae, she said, “Please let us in PIALA and those of you from these [Pacific] institutions work together to find practical and affordable solutions to address the critical need for staff development training in the region.”^[12]

Currently, there is only one active library skills training program in Micronesia at Palau Community College. The only one certificate/diploma program in the rest of the Pacific Islands is provided through the University of the South Pacific. In the recent past, there was an undergraduate School Librarianship program at the University of Guam, however, due to lack of university support, it is now defunct. The closest campus offering a Master in Library Science is the University of Hawaii.

Beginning in 1994, PIALA began to actively address this critical problem by providing the first preconference 2 day workshop on collection development for small libraries, given by Dr. Harry Uyehara, a noted librarian in Guam. In 1995, another pre-conference workshop was presented by two noted archivists, Karin Brennan from the University of New South Wales in Sydney, Australia and John C. Wright from Honolulu, Hawaii. The 2 day workshop dealt with the practical care of books, preservation, and disaster preparedness and recovery. At the following year’s conference, both pre- and postconference workshops were presented and now are an integral part of all PIALA conferences, covering a wide range of topics.

Although these PIALA pre- and postconference workshops attempt to fill a gap, there still remains the serious lack of opportunities for education and training leading up to a credential or professional degree.

RESOURCE SHARING

One of the purposes stated in PIALA’s *By-Laws* is “To foster awareness and encourage cooperation and resource sharing.”^[4] In a 1998 paper, the authors observed that “perhaps the most important impact of PIALA has been the increase of networking and resource sharing among the members.”^[13] However, before one can do resource sharing, one must know who is out there and what they have. Given the geographical vastness and lack of easy communications, when PIALA was established, very few in the Pacific Islands knew who was out there and what resources were where.

To address this critical need, one of the first projects PIALA undertook was compiling a list of regional libraries and in 1993, the *Directory of Libraries, Archives, and Museums in Micronesia*^[14] was published. This was the first comprehensive regional directory ever done. Subsequently, in 2003, the content became part of a bigger online project undertaken by the National Library of Australia, *Libraries of Asia and the Pacific Directory*<http://www.nla.gov.au/lap> (accessed September 2008). The online resource allows libraries to update and amend their own entries whenever needed. However, since many Pacific Islands do not have reliable, or in some cases, any Internet access, a print edition^[15] was published, funded by IFLA from a grant submitted by PIALA, in cooperation with the National Library of Australia and the Secretariat of the Pacific Community.

The first attempt to compile a regional union catalog came about with the help of Daniel Peacock’s LSCA funds when a bibliography of reports, surveys, and studies dealing with the Trust Territory was compiled and published.^[16] Throughout the ensuing years, there were scattered lists of serial holdings throughout the region. The first attempt to draw these serials holdings together was in 1997 with the publication of the *Union List of Serials in Libraries in Guam and Micronesia*.^[17] The collection of content for this publication was done with the support of PIALA members realizing the value of a union list for resource sharing. The latest edition published in 2002 and titled the *Union List of Serials in Pacific Islands Libraries*^[18] was expanded and now contains the holdings of both the University of the South Pacific Library in Suva, Fiji, and the Secretariat of the Pacific Community Library.

LIBRARY ASSOCIATION LINKAGES OUTSIDE OF MICRONESIA

As Goetzfridt wrote when referring to meeting the needs of the public, “the Pacific Islands Association of Libraries and Archives (PIALA) established an organizational paradigm of unity for Micronesia.”^[19] As PIALA has matured that unity has expanded to include other library associations both inside and outside the Pacific Islands working toward meeting those needs, as discussed below.

International Federation of Library Associations and Institutions

In 1996, PIALA was first represented at the IFLA Conference in Beijing, China^[20] and the following year, the author of this entry was elected as the PIALA representative to sit on the *IFLA Roundtable for the Management of Library Associations* (RTMLA), which later became MLAS. In 1998, the author became the RTMLA (then MLAS) Secretary and continued in that position until 2005.

In 2004, PIALA nominated Mark Perkins from New Caledonia to stand for election to the *Regional Standing Committee for Asia and Oceania*. He was elected with his term beginning in 2005. Then, in 2006, PIALA nominated three members to stand for election to IFLA Standing Committees and all were elected. Tamina Noddy from Papua New Guinea became a member of the *Management of Library Associations Standing Committee*; Libby Cass from Fiji was elected to the *Regional Standing Committee*

for Asia and Oceania; and Mark Perkins was elected to the *Free Access to Information and Freedom of Expression Committee*, each with terms beginning in August 2007.

Throughout the years, PIALA has applied for and received several grants from IFLA for publications, workshops and attendance at both PIALA and IFLA conferences.

Swedish Library Association

For several years, PIALA's IFLA membership was supported by the *Swedish Library Association*, under the visionary leadership of their Secretary General Christina Stenberg. She hoped this would serve as a model within IFLA for library associations in developed countries to encourage library associations in developing areas to engage with IFLA. This arrangement allowed PIALA members to see the benefits of IFLA membership before the major financial decision to join IFLA was made by PIALA. In 2001, PIALA voted to become a self-supporting member of IFLA and has maintained their membership since.

Moreover, without the additional financial support of the *Swedish Library Association*, PIALA's participation in the *RTMLA* and later the *MLAS* meetings between 2000 and 2004 would not have been possible. This too was part of the *Swedish Library Association's* effort to model library associations in developed countries supporting the participation of officers on IFLA Sections from developing areas.

Hawaii Library Association

Throughout the years, participants from Hawaii have attended and participated in PIALA conferences, conducting workshops, presenting papers, and providing support.

In 1998, inspired by the *America Library Association* President Barbara Ford's theme *Global Reach, Local Touch*, the *Hawaii Library Association (HLA)* and the *Pacific Islands Association of Libraries and Archives* formed an international partnership. This relationship was formalized in a resolution passed on November 2, 1998 by the *HLA* Executive Board, followed by another resolution passed by the PIALA Executive Board on November 19, 1998. The ALA Chapter Relations Office was informed of the partnership and the resolutions appear on the PIALA www page <http://piala.org.googlepages.com/history> (accessed September 2008).

American Library Association

Although individual PIALA members were involved with ALA throughout the years, it was not until 2005 that ALA became actively involved with PIALA. At that time, ALA took on a leadership role in the *IFLA Management of Library Associations Section* and funded the author's

participation as Secretary of the section at the 2005 meetings, much as was previously done by the *Swedish Library Association*.

Soon after, thanks to funding from IFLA and ALA, the *2006 Library Advocacy Workshop*, described elsewhere in this entry, was a pivotal event in bringing ALA to the Pacific Islands. Stemming from that involvement, in 2007, when judging was over for ALA's *Outstanding Reference Books* competition, ALA donated many of the reference books to the Palau Community College Library. Hopefully, this relationship will continue to the benefit of both associations.

Fiji Library Association

Several *Fiji Library Association* members have participated and presented papers at PIALA Conferences throughout the years. Recently, PIALA and the *Fiji Library Association* worked together to request the *Australian Library and Information Association* to develop a sponsorship program for Pacific Island librarians to attend the 2010 IFLA Conference in Brisbane, Australia.

OTHER LINKAGES

To foster greater unity between library associations, PIALA representatives have participated in many library conferences throughout the world. In addition to the many IFLA, HLA and ALA conferences where PIALA has participated as early as 1994, PIALA participated in the 1994 joint *New Zealand Library and Information Association and the Australia Library and Information Association Conference* in Wellington, New Zealand. PIALA also participated in both the *8th Interlending & Document Supply Conference* in 2003 in Canberra, Australia and the *10th Interlending and Document Supply Conference* in 2007 in Singapore.

Most recently, PIALA was invited to participate in the *11th Aboriginal and Torres Strait Islander Library Information and Resource Network (ATSILIRN) Conference* in Darwin Northern Territory, Australia in 2008. These events each broaden the network and increase awareness of PIALA and the issues faced in Micronesian libraries.

Pacific Resources for Education and Learning

Pacific Resources for Educational and Learning (PREL), an independent, nonprofit agency based in Honolulu and serving the educational communities in Micronesia, has been supportive of PIALA for many years. In 2000, PREL funded a librarian from the Solomon Islands to present a paper about the Forum Fisheries Agency Library at the PIALA 2000 Conference in Guam.^[21] Throughout the years, PREL representatives have attended PIALA conferences and presented papers and workshops.

In the past several years, PREL has funded several training initiatives for librarians in the region. Most recently, a successful 3 day workshop on disaster preparedness, response and recovery was held in conjunction with the PIALA 2007 Conference in Tinian, Commonwealth of the Northern Mariana Islands. This workshop was the first to be presented with funding from a 3 year United States Institute of Museums and Library Services grant entitled *Leaders for Pacific Libraries*. The grant included three, 3 day subject-specific workshops held in conjunction with PIALA annual conferences, providing the opportunity for workshop participants to attend the PIALA Conference, as well.

OTHER NOTABLE EVENTS

The PIALA Lifetime Achievement Award

The PIALA Lifetime Achievement Award was created by a resolution passed by the PIALA Executive Board 1997 at the annual meeting in Pohnpei. This award was designed to “honor librarians and lay persons who have made a substantial and integral contribution to libraries and librarianship in the Western Pacific.”^[22]

In 1998, the award was first bestowed on Daniel J. Peacock, former Director of Library Services for the Trust Territory of the Pacific Islands. In 2006, Dr. Karen Peacock, the University of Hawaii Library Head of Special Collections and Pacific Collection Curator was the second recipient of the award. Most recently in 2007, the author, who was then the University of Guam Robert F. Kennedy Memorial Library Circulation and Interlibrary Loan Librarian, was presented the award.

Florence Nalezny Warpeha Memorial Books to Micronesian Libraries

The PIALA 1997 Conference in Pohnpei saw the beginning of the *Florence Nalezny Warpeha Memorial Books to Micronesian Libraries*. Every year, Rita Warpeha, formerly a librarian at the Pohnpei Public Library, would donate a selection of Micronesian and Pacific Island-related natural science children's books in memory of her mother. The donations continued until 2003 and the books found homes in local libraries on the island hosting the annual conference.

Dakio Syne Memorial

Dakio Syne, the Director of the College of Micronesia—FSM Learning Resources tragically passed away in 2002. He was a founding member of PIALA and PIALA's first President, as well as the first Micronesian to earn a master's degree in library science in 1976 from New York University. In his honor, the *Dakio Syne Memorial Fund*

was set up to help fund a Micronesian librarian's first attendance to PIALA. Also, PIALA supported the publication of a book memorializing him and his work.^[23]

CONCLUSION

The Pacific Islands Association of Libraries and Archives was established 17 years ago as a voluntary association of dedicated people sharing many hopes and challenges. Yvan Souares, a Pacific Islands epidemiologist summed up well the challenges when he wrote,

“These islands are scattered over 30 million square kilometers of the Pacific, an area almost four times that of Australia. Ninety-eight percent of that area is water, leaving a total land area only half that of the Northern Territory of Australia. For seven million Pacific people, the development of human networks in these conditions is both a challenge and a prerequisite to socio-economic development.”^[24]

Although he was writing about health care workers throughout the entire Pacific, these human networks are just as profoundly important to people working in libraries, archives, museums within Micronesia. With the establishment and growth of PIALA, in the face of the major economic, communication, and training challenges, the human networks are alive and thriving, expanding borders to throughout the Pacific Islands. As these networks continue to grow, we all benefit in access to the information and resources needed for socioeconomic development and personal well-being.

ACKNOWLEDGMENTS

A heartfelt thanks to Joanne Tarpley Crotts and Karen Peacock who helped give birth to PIALA; Iris Falcam for her willingness to share her wisdom; Mark Perkins, for his helpful insights; Elisabeth Newbold for her fresh look at the manuscript, Marcia Bates for her encouragement, and my husband Steve for his patience while I sat at my computer. They all had their part in making this piece come to life. And, to all who worked to grow PIALA these past 18 years, so this entry could exist.

Papyrology

Roger S. Bagnall

Institute for the Study of the Ancient World, New York University, New York, New York, U.S.A.

Abstract

Papyrology is the science of preserving, reading, and interpreting ancient texts written on papyrus. It includes texts written on other materials using ink. The majority of preserved papyri come from the first millennium B.C. and the first millennium A.D.; most are in Greek, but many texts in Egyptian and other languages also survive. They contribute to our knowledge of ancient literature and books, as well as practically every aspect of ancient history, including especially social, economic, and cultural history.

INTRODUCTION

Papyrology is the science of preserving, reading, and interpreting ancient texts written on papyrus. The field historically dealt particularly with those papyri written in Greek or Latin; those in other languages were often considered part of the domains of Egyptology and Semitic studies, but papyrology has increasingly included a wider range of languages and materials; studies of papyri in Demotic Egyptian, Coptic, and Arabic are now active parts of the discipline. This entry explains what papyrus is, how it was used in ancient times and is treated today, how the discipline of papyrology works with papyri and other ancient textual supports, where papyri are published, and what contributions the work of papyrologists has made to the study of literature, history, and language.

THE PLANT AND THE PAPER

The writing material is made from the fibers of the reed *Cyperus papyrus*; strips are cut from the stalks, laid side by side, first in one direction and then on top of these at a right angle. They are pressed together so that the natural juices of the plant flow, acting as a binding agent. After drying, the resultant pieces provide a smooth, flexible, light-colored, and durable writing surface. Typically, a number of such pieces would be glued end to end (with small overlaps) to make a roll, which was the standard form of papyrus for commerce and book production. For documents of smaller than roll size, pieces would then be cut from the roll to the desired dimensions.

Paper from papyrus was manufactured by the Egyptians as early as the fourth millennium B.C.; for various reasons (partly the circumstances of preservation), the papyri that have survived to modern times come largely from the first millennium B.C. and the first millennium of the present era, although there are some notable earlier literary, documentary, and funerary texts in Egyptian.

Papyrus came to be used less and less after the Byzantine period, for reasons that are not fully understood (see “Contributions of Papyri: Literature,” subsection “History of the Book”). Whether as cause or effect, the papyrus swamps in Egypt, which were the source of the raw material of the paper industry, gradually silted up and disappeared from Egypt so that the plant is now found growing wild only in an area 500 miles up the Nile in Ethiopia. It has been reintroduced in Egypt and elsewhere in modern times.

Papyrologists also deal with texts written on certain other materials: potsherds (*ostraka*), wood, waxed tablets, leather rolls, and parchment. Writing on stone and metal, on the other hand, is considered to belong to the province of epigraphy. The division between the two disciplines is sometimes indistinct.

THE REDISCOVERY OF PAPYRI

Although a certain number of papyri continued to be preserved in archives in Europe through the Medieval Period, the Western world lost awareness of papyri during this period, and not until the eighteenth century did papyri come back to the attention of Europe. In Herculaneum, in 1752, a villa was found in which numerous carbonized rolls of papyrus from a private philosophical library were preserved. When to the difficulty of unrolling the brittle texts was added the disappointment of the literary world at the failure of the rolls to contain famous lost works of literature, the papyri of Herculaneum receded from the public view. (The study of these papyri, mainly works of the Epicurean philosopher Philodemus, has had a notable resurgence in the last 30 years.) No less disappointing to scholars of the time was a papyrus roll brought back from Egypt in 1778 that turned out to be an account of laborers on irrigation works rather than a lost play of Sophocles or some such.

It was not until the middle of the next century that a few sizable collections of papyri in Europe were formed

and published, notably those of London, Leiden, Paris, and Turin. Then in the last quarter of the nineteenth century, numerous finds were made and a vast expansion of papyrus collections in Egypt, Europe, and North America was underway. Over the next 60 years, hundreds of thousands of texts, often fragmentary, were found, both literary and documentary, from organized or clandestine excavations. The largest number of papyri comes from Middle Egypt, particularly Oxyrhynchus (modern Bahnasa) and the Fayûm, a low-lying area to the southwest of Cairo, but other finds have ranged from the Nubian frontier in the northern Sudan to the Delta. Few papyri, however, have been excavated in the Delta and other regularly irrigated areas, because of the destructive effects of water on papyrus; desert areas (especially tombs) and once-cultivated but now dry regions have been the most productive. From Alexandria, the capital, we have only a small number of texts found in other areas (sometimes sent there as waste paper for wrapping mummies—cartonnage, as it is called).

Outside Egypt, significant finds of papyri have been made at Dura-Europos and elsewhere in the Euphrates valley in Syria (mostly from the third century of our era), from Nessana in the Negev (late Byzantine period), in the area of the Dead Sea, at Petra (Jordan, also Byzantine), and in Italy the carbonized papyri of Herculaneum already mentioned. A very early carbonized roll (fourth century B.C.) was found in a tomb at Derveni in Macedonia. Unsuitable climatic conditions have caused papyri to be destroyed in most areas, but more finds may yet be made in countries with desert regions similar to Egypt. Ostraka are found more widely, from North Africa to Iran, and parchment documents have been found from late antique Bactria and other parts of the Near East and Central Asia. Wooden tablets with ink texts have been excavated in England, at the Roman military camp at Vindolanda, where anaerobic conditions preserved them.

COLLECTIONS OF PAPYRI

There is no full census of collections and their contents available, for papyri are usually made known only when published in full, and the process of publication is slow. The largest collection is probably the Oxyrhynchus papyri (in the Sackler Library, Oxford, from Grenfell and Hunt's excavations a century ago), not yet fully inventoried, the next that in the National Library in Vienna, formed by the Archduke Rainer by purchases 75 to 100 years ago; its total number of objects, in many languages, is around 180,000. There are many collections in Germany, with the largest in Berlin, and others in Heidelberg, Cologne, Munich, Freiburg, Jena, Leipzig, and Trier. The principal French collections are those in Paris, Strasbourg, and Lille; in Italy in Milan, Florence, and the Vatican; in England in London, Oxford, and Manchester; and in

Scandinavia at Oslo and Copenhagen. Egypt itself possesses one of the largest collections in the Egyptian Museum in Cairo and smaller ones in the Coptic Museum (Cairo) and Graeco-Roman Museum in Alexandria. In North America, the largest collection is at the University of Michigan, and smaller but important ones exist at Berkeley, Yale, Columbia, Duke, and Princeton. Still smaller but significant collections are at New York University, Washington University, Toronto, Pennsylvania, and others. Many American colleges have small groups of papyri distributed by the Egypt Exploration Fund in the early part of the century. There are also private collections in many countries, mostly small but occasionally (as with Martin Schøyen in Norway) quite large.

TREATMENT OF PAPYRI

Papyri are commonly in bad condition when found—torn, full of holes, wadded together, dirty, folded, and even charred. Relatively simple problems can be solved by humidifying the papyri and manipulating them in this condition, allowing them to dry only when clean and straightened. For cartonnage, a technique has been developed whereby a dilute solution of an enzyme is used to dissolve the adhesive between sheets within a few minutes. Papyri of any size are normally best preserved between thin sheets of glass, held together with clips or tape, although folded acid-free paper or blotting paper may be an acceptable short-term substitute for little-handled materials. Like other old paper materials, they benefit from storage out of the light and in controlled temperature and humidity conditions.

Various aids can be used in reading texts that are not clear to the naked eye: first, simple magnifiers, then if needed, more powerful microscopes. Photography by infrared or ultraviolet is sometimes helpful, and even conventional photography can on occasion, by long exposure time, make faint ink traces appear more clearly. Digital photography has largely displaced film; multispectral imaging allows more precise targeting of the wavelength of ink and sometimes the recovery of effaced or hidden ink.

RESEARCH AND RESEARCH FACILITIES

The beginning of the study of a treated papyrus is reading it. This is an easy or difficult task depending on the physical condition of the papyrus, the difficulty of the handwriting, the clarity or obscurity—and sometimes, the vulgarity—of the writer's language, the nature of the contents, and the skills of the reader. The papyrologist's task is not so much to read individual letters and words as to grasp the thought of the writer; once that is understood, the words can be read more easily. In a banal standardized document (e.g., a lease) this can often be very easy, while

a very individual, private letter may resist all attempts at understanding. The reading of a text is thus inseparable from the work of translation and commentary, which sets forth the editor's understanding of the text. In the commentary to a papyrus one finds an explanation of its general import and contribution to our knowledge, as well as a detailed examination of problems in the language or contents.

The publication of the annotated and translated text is only the start, however. Because of the many difficulties of reading and understanding papyri, few texts are so perfect when published as not to need correction. And a published text may give rise to extensive studies of its literary, historical, juristic, economic, or social implications: studies that often finish by correcting the texts.

To carry on the various stages of this work, the papyrologist needs good light, a magnifying glass, and sometimes a microscope, but above all, a complete collection of the already-published papyri of other collections. These volumes (see section on "Publication"), together with the special lexica, grammars, prosopographies, indices, and monographs in the field, form the indispensable working library of the papyrologist. In the course of a few hours work, one may consult dozens of volumes to check references to possible parallels to a phrase or an institution, and only the assembly of the requisite books in one place for easy consultation can make serious papyrological research possible; such studies have flourished only where special working libraries could be created. Particularly good collections in North America of this sort exist at Michigan, Columbia, Duke, Toronto, and Yale—not surprisingly, the places where actively worked collections are found. The Greek documentary texts on papyrus have been digitized in the Duke Databank of Documentary Papyri, allowing scholars to find words and names relatively easily, and the Heidelberger Gesamtverzeichnis der griechischen Papyrusurkunden Ägyptens provides a typological catalog useful in finding parallel texts. Similar tools for other languages are at various stages of development and completeness. Many papyri are available on the Web in digital images. But the full editions, with commentary, are still available almost entirely in book form. That limitation may be expected to be removed in time, making it far easier to conduct research in places far removed from major libraries.

PUBLICATION

All modern editions of papyri follow, in essentials, the form outlined above: introduction, text, translation, and line-by-line commentary. These texts are published primarily in volumes uniting many papyri from one collection, provenance, or archive. Publications by the place of finding include notably the *Oxyrhynchus Papyri* (now 70 volumes with over 4800 texts) and the *Tebtunis Papyri*

(5 volumes with over 1100 texts); specific archives are numerous, the largest being that of Zenon, an estate manager of the third century B.C., which is scattered in several collections and numbers around 2000. Other large collections published are the Michigan papyri, the collection of Florence, the Berlin papyri, and several series of volumes of Cairo papyri. Papyrologists have a standard set of abbreviations for these volumes (e.g., *P.Oxy.* = *The Oxyrhynchus Papyri*).

Many other texts are published for the first time in journals. These are periodically reprinted in the *Sammelbuch*, started by Fr. Preisigke, which indexes them as well. More than 20,000 texts (inscriptions as well as papyri) are printed and indexed in the 26 volumes that have appeared so far. Preisigke also started another publication that records, in more or less systematic fashion, conjectures and corrections to papyri and *ostraka*, scattered through the literature. More details on this and the other essential reference works of the subject are given in the bibliography.

CONTRIBUTIONS OF PAPYRI: LITERATURE

History of the Book

Papyri provide virtually all of our firsthand evidence about the form and character of ancient books. The usual form of the book was a roll of papyrus on which a succession of columns of writing was placed, so that the reader would start with the outer edge of the inside face, unrolling the papyrus as he went, rolling up again from the other side. (In Egyptian the texts on these rolls generally run from right to left, in Greek from left to right.) Practical considerations limited the amount that could be written on one roll, and the cumbersomeness of referring to a location inside a roll encouraged the habitual practice of giving references to other authors only by the "book" (i.e., roll), with no further precision.

About A.D. 100, we get the first examples of the codex, the forerunner of the modern book with pages created from folded sheets and opening from a common spine. The codex appears to have originated in Rome in imitation of notebooks of tablets. It was popular in the Christian community in the early centuries A.D. and was used for scriptural texts almost to the exclusion of the roll. Later, and gradually, it came into much wider use for all kinds of books and for some types of documentary records, perhaps under Roman influence. Increasingly, parchment was also used for making codices, perhaps because it resisted wear and tear along edges better than papyrus. But because parchment was more expensive than papyrus, parchment books remained luxury items.

Many examples of both types of books have been found, whether largely complete or (more commonly) badly damaged, among the papyri. They show us not only

the form of the book but its characteristics, notably the handwriting (book-hands are normally neat, carefully written scripts) and the critical marks (full or partial accentuation of Greek appears for the first time in a few papyri, above all in educational contexts). From these, we are able to form a more accurate idea of the type of manuscript that lies behind the medieval ones through which most ancient literature is preserved.

Greek Authors

The range of literature in circulation in Hellenistic and Roman Egypt was much larger than what survives to our day in medieval manuscripts, and numerous discoveries, occasionally of complete or nearly complete works—but more often of scraps—have considerably enriched our store of Greek literature over the last 100 years. Among authors or works found in significant amounts are lyric poets, especially Bacchylides, Sappho, Archilochus, and Alcaeus; the Athenian orator Hyperides; the comic dramatist Menander (of whom previously only fragments had survived); the “Constitution of Athens” by Aristotle; Callimachus; the *Hellenica* from Oxyrhynchus by a historian of the fourth century B.C.; the Epicurean writings by Philodemus found at Herculaneum; Herodas; a satyr play by Sophocles; and the epigrams of Poseidippos. Some of the paraphernalia of ancient learning have also appeared to increase our knowledge, such as lists of initial lines of plays; lists of Homeric vocabulary, which was obscure already in ancient times; summaries of works; and the like. Through these we get valuable information about lost works and come to understand how the ancient reader approached texts.

The majority of the literary papyri discovered and identified give us texts from works already known; besides informing us on the character of ancient books, these give us an idea of the reading habits of the literate public in Hellenistic and Roman Egypt. The *Iliad* of Homer was by far the most popular work, with the *Odyssey* next. After Homer come Demosthenes, Euripides, Callimachus, Hesiod, Isocrates, Plato, Thucydides, Aeschylus, and Xenophon. Many more authors have more than one papyrus each, and another large group just one apiece. Well over 100 authors—to count only those identified—were read even in provincial Egypt. The literate Greeks of the period thus had available to them a considerably larger selection than survived the Middle Ages. At the same time, we see that very few works were *commonly* read that have not survived in medieval manuscripts.

Almost half of all literary fragments have not been assigned with certainty to a known author and work. Sometimes this results from our knowing too little about the works of authors whose books have not otherwise survived; the *Hellenica Oxyrhynchia*, of which we have a sizable amount but whose authorship is disputed, is an example. Most often, the fragment is very small and, in

the absence of its discovery in a known work, the preserved material is so small as to make an attribution to an author (about whom little may be known) very difficult, even impossible. Many fragments have, however, been assigned to known authors in the past two decades since the corpus of classical Greek literature became available in digital form (the *Thesaurus Linguae Graecae*) and thus easily searchable even for brief sequences of letters.

Religious Literature

Numerous papyri have preserved parts of the texts of the Old and New Testaments, contributing considerably to the study of the earliest form of these texts. Many other Greek and Coptic papyri of theological or liturgical significance have been found, including many witnesses to the diversity of the early Christian tradition, in particular the *Sayings of Jesus* from Oxyrhynchus, and the Gospel of Thomas from the important find of Coptic Gnostic texts at Nag Hammadi and the Gospel of Judas from a separate discovery in Middle Egypt. Other apocryphal gospels have also been found. The history of the New Testament is further illuminated by early manuscripts of the gospels and by a fragment of Tatian’s *Diatessaron*, giving an attempted harmonization of the four gospels (with some apocryphal material), found at Dura-Europos.

The early centuries of Christianity in Egypt are also illuminated by some outstanding discoveries, notably two major works of Origen and a large number of commentaries on the Old Testament by Didymus the Blind, found in the Tura quarries near Cairo.

Many aspects of other religions also gain from the papyri; those from Egypt provide much information on the life of Jews in Egypt, and the finds from the Dead Sea region in Palestine make a more direct contribution to the study of Judaism in the first two centuries. Major finds of Manichaean texts have transformed our knowledge of that religion. In pagan religion, there is a wealth of information varying from hymns to priestly practices to organizations of cultic associations. Magic and astrology are well represented in the papyri, with horoscopes and spells well known.

CONTRIBUTIONS OF PAPYRI: HISTORY

Political History

Most of the thousands of documents found concern affairs internal to Egypt and usually local in character. The history that they yield is largely the story of the otherwise unknown landowners, small farmers, businessmen, soldiers, and other ordinary people, a story entirely ignored by the “historical” writings that we have from antiquity. There are exceptions, cases in which the papyri provide us with important facts about the main course of politics,

war, and diplomacy. It is, for example, from papyri that most of our information about the chronology of the Ptolemaic kings comes. From the archives of Zenon (see section on “Publication”), we hear of court intrigues, diplomacy with the Seleucids, and the government of the Ptolemaic empire. A report by Ptolemy III gives a narrative of part of the Syrian War of 246–241.

The several native revolts and civil wars of Ptolemaic Egypt are documented in the papyri, especially by repeated royal amnesty decrees such as the well-preserved edicts of 118 B.C. and by some correspondence from troubled periods. Typically, we get, from the papyri, not an overview but rather the effects that historical events had on some individuals.

From the Roman period, with its larger number of papyri, we derive correspondingly more abundant information. We learn the names and dates of the Roman governors of Egypt, and we have considerable information on the composition and activities of the garrisons they commanded. The political vicissitudes of Egypt in the turmoil of the later empire are reflected in the dating formulas used, giving us a degree of precision about shifts of allegiance difficult to come by in other provinces.

It is, however, more in the areas of institutions, social and economic aspects, and culture that the masses of papyri create for us, with a wealth of detail (but not always any generalizations!), a minutely detailed panorama of life. Particularly valuable are the surviving archives, groups of interrelated papyri, which taken together give us much greater insight than the individual documents could if isolated. Several examples are cited below.

Law and Institutions

We learn of the governing of Hellenistic and Roman Egypt, both in theory and in practice, from a considerable number of documents. Nearly a hundred Ptolemaic laws of various sorts are preserved in full or in extracts: city laws of Alexandria; royal decrees about subjects such as military service, slavery, taxes, police work, and judicial procedure; detailed regulations for the operation of the monopolized oil industry; and royal laws applicable to areas outside Egypt such as Syria and Phoenicia.

Under the Romans, we are no less richly benefited by legal texts on papyrus. The famous *Gnomon of the Idios Logos* (a collection of excerpts of imperial rulings and laws) gives the gist of the detailed and repressive code under which Roman administrators confiscated property, prohibited marriage between many groups, and enforced numerous aspects of Roman social policy. Imperial and prefectural edicts and responses to petitions set forth principles of law and their application, broad or narrow; some of the most famous are two edicts of Germanicus Caesar and some responses of Septimius Severus.

The detailed application of the law and the machinery through which it operated are revealed in numerous

records of court proceedings and in a host of related documents. One of the most famous is the dossier recording the feud between a Greek soldier and some Egyptian priests of the dead about a house in Thebes in Upper Egypt. The extensive knowledge of judicial procedure gained from these texts has led to scores of monographs and many works of synthesis. It is fair to say that the study of Greek and Roman law has been profoundly influenced in the last century by the papyri.

The other aspects of royal and imperial administration—finances especially—are shown in great detail by surviving official correspondence, petitions, accounts, memoranda, and other records. One of the most interesting archives is that of Menches, a village scribe in a Fayûm hamlet in the late second century B.C., struggling to maintain royal revenues in a time of declining agricultural production—and, above all, to protect his own position. His counterpart 300 years later, Petaus, is barely able to sign his own name, but his scribe-written files give us much information on such problems as compulsory public service in his period.

Society and Economy

The papyri offer no economic laws and few obvious generalizations, but they do give us thousands of transactions—leasing land, renting a house, selling crops, buying a slave, apprenticing one’s son or oneself, paying taxes, and much more. We see the major processes of the economy of Egypt from both the government’s side and that of the individual. In the so-called Revenue Laws papyrus, we find the detailed instructions for the maintenance of the crown monopoly on the production and sale of edible oils; elsewhere, we hear about smuggled oil and violation of other regulations. We find Ptolemaic soldiers selling plots of land that belong to the king rather than to them; we also have the royal edicts prohibiting this practice.

The economy of Egypt rested predominantly on the grain crop, and so it is the grain crop about which we hear most—its sowing, cultivation, harvest, taxation, and ultimately its sale or dispatch abroad for Ptolemaic foreign trade or the Roman grain dole. But we learn also of other industries like papyrus, of trade in rarer items like spices, of the trade through the Red Sea ports to India. In many cases, the evidence allows the distillation of statistics, though their reliability is not always secure.

The society of Egypt that we see in the papyri was a mixture of Greek and Egyptian, but only to a limited extent a blend of them. We find Greeks living in groups in towns, Egyptians mostly farming the land. The Greeks preserved their culture by various institutions (see section on “Culture”). Some Egyptians sought self-advancement through learning Greek and rising in the bureaucracy (or the Roman army), and some Greeks married native women and were essentially absorbed by Egyptian society. In general, the vast mass of Egyptians was only

slowly affected by any direct influence of Hellenism, but over time even such fundamental Egyptian habits as drinking beer gave way to the Greek preference for wine.

The Greek papyri, naturally, come predominantly from the part of society that could speak Greek, a group that included many Egyptians as time went on. The early Ptolemaic papyri reveal to us a still very Hellenic society, made up of immigrants and their children, but the more ambitious natives were added to it as time went on, and the Greek openness to the gods of their new country led to a growing adoption of personal names based on Egyptian deities. The longer the separation from the world of the Greek *polis* (city-state), the greater the tendency was to develop what we may call a Greco-Egyptian society, rather less centered on a privileged citizen body than the classical pattern and accepting many native customs. If more of our surviving documentation concerned the Greek cities, our view might be different, but it is the provincial towns and villages that are, above all, represented in the surviving texts.

Culture

The extent of literacy and reading among the Greeks in Egypt has already been discussed briefly. The Greeks sought to preserve a corporate and cultural identity by means of their educational institutions—schools, and especially the gymnasium, in which the young men of Greek families received the athletic training and other education to fit them for a place in Hellenic society. The gymnasium remained a center of community life for these men as adults, providing the focus for the athletic contests, which were such a prominent part of social activity. Fewer women received an education, but some were literate thanks to schooling whether at home or in a more formal school. Many papyri, ostraka, and tablets preserve examples of both teacher's models and student exercises from the schools of Egypt, allowing a detailed reconstruction of the process by which students learned to write and read, probably in that order.

A host of smaller private clubs existed among both Greeks and Egyptians to promote a congenial social atmosphere and to celebrate the cults of various gods. We find some evidence of Greek forms of entertainment in the papyri, such as flute players and comic actors, often hired for private parties.

Language

Fifty thousand Greek papyri and ostraka, together with thousands of texts in other languages, provide one of our major resources for understanding several ancient languages. The material is richest for the transformation of the language known in the classical Greek authors into that of modern Greece. There is still much to be done in the systematic study of this evidence, but already the

trends that are visible have been described in sufficient detail for it to be clear that the *koine* Greek of the New Testament was not a special language concocted for it alone, nor yet a heavily "semitized" Greek from Palestine, but rather a type of Greek abundantly illustrated by documents and letters, very characteristic of the actual language of its time. Similar insight has been gained into the language used by many literary figures of postclassical Greek antiquity.

The tendencies of the period are heavily in the direction of simplification, in part no doubt because of the absorption of many non-Greek peoples into the body of Greek speakers. The perfect tenses and the optative mood become rarer, and many irregular forms give way to newly formed regular ones. The vocabulary too changes; many Homeric words were sufficiently unknown in Roman times that readers of Homer would have special glossaries at hand to help. The nature of papyrus texts has led to a knowledge of many classes of words connected to everyday life that literary sources do not use, thus broadening our knowledge of the language. Conversely, the papyri shun much of the elaborate vocabulary of classical Greek, especially of poetry.

The other languages found in the papyri were in some cases written mainly by trained professionals (as in the case of Demotic Egyptian) according to rules that changed far more slowly than did the spoken language. The last written form of Egyptian, Coptic, is recorded in many documents of everyday life that give a vivid sense of something closer to the spoken vernacular of the time, which had absorbed many Greek words. And early Arabic papyri show how the language was written at a time when the written form familiar today was not yet fully fixed.

CONCLUSION

Papyri are an important part of our written heritage and document several major steps in the development of human communication. Papyrus was a crucial element in the organization of one of the earliest complex societies, the first reasonably portable means for recording man's memory, the most convenient way of transporting information across distances, and the vehicle by which large portions of the ancient world came to have more than perfunctory literacy. In the papyri, we find, more than in any other source, the material for a direct understanding of the daily life of ordinary people in antiquity. Although papyrus gave way to parchment and paper after four millennia of use, the shape of books in paper remained the codex, one of those for which papyrus was employed, and only the invention of movable type changed significantly the style of communication that papyrus represents in the history of the Western world.

ACKNOWLEDGMENTS

The principal international organization in the field is the Association Internationale de Papyrologues, with headquarters in Brussels (<http://www.ulb.ac.be/assoc/aip/>). Its American affiliate is the American Society of Papyrologists (Department of Classics, University of Cincinnati, Cincinnati, OH 45221; <http://classics.uc.edu/asp/>). The International Association of Coptic Studies (<http://rmcisadu.let.uniroma1.it/%7Eiacs/>) and the International Society for Arabic Papyrology (<http://www.ori.unizh.ch/isap.html>) deal with specific parts of the field.

BIBLIOGRAPHY

1. Introduction: E.G. Turner, *Greek Papyri* (Clarendon, Oxford, 1968) is the standard introduction in English. O. Montevecchi, *La papirologia* (2nd ed., Vita e Pensiero, Milan, 1983) is useful for bibliography and lists.
2. The plant: N. Lewis, *Papyrus in Classical Antiquity* (Clarendon, Oxford, 1974), with a *Supplement* (Fondation Egyptologique Reine Elisabeth, Brussels, 1989) is the standard work on the plant, its uses, and the writing material. See also Richard Parkinson and Stephen Quirke, *Papyrus* (Austin, 1995). For *ostraka*, see U. Wilcken, *Griechische Ostraka aus Aegypten und Nubien* (München, 1899), Vol. 1. Many papyri are now available in digital images; see the Advanced Papyrological Information System. Available at <http://www.columbia.edu/cu/lweb/projects/digital/apis/index.html>, with other resources listed there.
3. Discoveries: A general survey of the history of papyrology is given by F.G. Kenyon, "Fifty Years of Papyrology," *Actes du Vc Congrès International de Papyrologie, 1937* (Brussels, 1938) 1–11. Chapter 2 of E.G. Turner, *Greek Papyri* (Clarendon, Oxford, 1968) is more detailed. A fuller survey is K. Preisendanz, *Papyrusfunde und Papyrusforschung* (Hiezeemann, Leipzig, 1933). For papyri from Dura-Europos: *Excavations at Dura-Europos, Final Report V, Part I: The Parchments and Papyri*, C.B. Welles, R.O. Fink, and J.F. Gilliam, eds. (Yale Univ. Press, New Haven, 1959). For Nessana, see *Excavations at Nessana*, H.D. Colt, L. Casson, E.L. Hettich, and C.J. Kraemer, Jr., eds. (Princeton Univ. Press, Princeton, 1950–1962, 3 vols.). For Petra see J. Frösén, A. Arjava, and M. Lehtinen, *The Petra Papyri I* (American Center of Oriental Research, Amman, 2002); additional volumes are forthcoming.
4. Collections: The most useful list of papyrus collections is now the *Leuven Homepage of Papyrus Collections*. Available at <http://www.trismegistos.org/coll.php>.
5. Treatment: See Jörg Graf, Myriam Krutzsch, *Ägypten lesbar machen—die klassische Konservierung/ Restaurierung von Papyri und neuere Verfahren* (De Gruyter, 2008). For the extraction of papyri from cartonnage see J. Frösén, chapter on conservation in R.S. Bagnall, ed., *The Oxford Handbook of Papyrology* (Oxford U.P., New York, 2009). For formal standards for conservation generally, see Advanced Papyrological Information System, Guidelines for Conservation of Papyrus, Leyla Lau-Lamb, ed. (University Library, University of Michigan, Jan. 2005) Available at <http://www.lib.umich.edu/pap.conservation/guidelines.html>.
6. Research and facilities: For an introduction to the work of reading a papyrus text, see H.C. Youtie, "The Papyrologist: Artificer of Fact," *Greek Roman and Byzantine Stud.*, **4**, 19–32 (1963); a more detailed exposition is found in his *Textual Criticism of Documentary Papyri* (Inst. Class. Stud., London, 1974). The other aspects of papyrology are adequately illustrated by the material cited under *Literature* and subsequent headings.
7. Publications: The standard list of papyrus editions, with usual abbreviations, is J.F. Oates et al., *A Checklist of Editions of Greek, Latin, Demotic, and Coptic Papyri, Ostraca, and Tablets* (5th ed., David Brown Book Company, Oakville, CT, 2001); an online version is kept current Available at <http://odyssey.lib.duke.edu/papyrus/texts/clist.html>. The *Oxyrhynchus Papyri* were edited first by A.S. Hunt and B.P. Grenfell, later by many other scholars; they are published by the Egypt Exploration Society (London) in its Graeco-Roman Memoirs. The volumes of the *Tebtunis Papyri*, edited by the same scholars and others, also appeared in this series. For the Zenon archive, see Cl. Préaux, *Les Grecs en Egypte* (Off. de Publicité, Brussels, 1947) and C. Orrieux, *Les papyrus de Zénon: l'horizon d'un grec en Egypte au IIIe siècle avant J.C.* (Macula, Paris, 1983). The other series of papyri are listed in the *Checklist*. Preisigke's collection of corrections is the *Berichtigungsliste der griechischen Papyrusurkunden* (now E.J. Brill, Leiden, 1915–), now in 11 volumes. The principal bibliography is M. Hombert, G. Nachtergaele, and A. Martin, *Bibliographie Papyrologique*, available for 1932– (CD-ROM plus quarterly updates; Association Egyptologique Reine Elisabeth, Brussels). For Demotic, see M. Depauw, *A Companion to Demotic Studies* (Association Egyptologique Reine Elisabeth, Brussels, 1997).
8. Literature: The standard listing of literary texts is R.A. Pack, *The Greek and Latin Literary Texts from Graeco-Roman Egypt* (Michigan, Ann Arbor, 1965), now essentially replaced by a digital version prepared by P. Mertens et al. ("Mertens-Pack3") Available at <http://www.ulg.ac.be/facphl/services/cedopal/pages/mp3anglais.htm>. A fuller online-only database of literary works is the Leuven Database of Ancient Books. Available at http://ldab.arts.kuleuven.be/ldab_text.php. On the history of the book, see F.G. Kenyon, *Books and Readers in Ancient Greece and Rome* (Clarendon, Oxford, 1951); W. Schubart, *Das Buch bei den Griechen und Römern* (Koehler und Amelang, Leipzig, 1961); C.H. Roberts, "The Codex," *Proc. Brit. Acad.*, **40**, (1954); W.A. Johnson, *Bookrolls and Scribes in Oxyrhynchus* (Toronto, Univ. of Toronto Press, 2004). The Tura papyri are mostly published in the series *Papyrologische Texte und Abhandlungen* (Habelt, Bonn, 1968). Texts concerning Jews in Egypt and elsewhere are collected by V. Tcherikover and A. Fuks, *Corpus Papyrorum Judaicarum* (Harvard, Cambridge, MA., 1957–1964, 3 vols.).
9. History: The information on Ptolemaic Egypt is in considerable part collected systematically in the *Prosopographia Ptolemaica* of W. Peremans, E. Van't Dack et al. (Publ.

Univ., Louvain, 1950, 10 vols. to date; on line. Available at <http://prospol.arts.kuleuven.ac.be/>). A good series of case-studies can be found in N. Lewis, *Greeks in Ptolemaic Egypt* (Clarendon, Oxford, 1986). Works on Roman Egypt are numerous; see collections of documents on the army by S. Daris, *Documenti per la storia dell' esercito romano in Egitto* (Vita e Pensiero, Milan, 1964); and R.O. Fink, *Roman Military Records on Papyrus* (Amer. Phil. Assoc., Monograph 26, 1971), and the synthesis of N. Lewis, *Life in Egypt under Roman Rule* (Clarendon, Oxford, 1983). For history and the papyri see generally A.K. Bowman, *Egypt after the Pharaohs* (British Museum, London, 1986) and R.S. Bagnall, *Reading Papyri, Writing Ancient History* (Routledge, London, 1995), with bibliography. For the Demotic contribution, see Friedhelm Hoffmann, *Ägypten Kultur und Lebenswelt in griechisch-römischer Zeit: Eine Darstellung nach den demotischen Quellen* (Akademie Verlag, 2000). For Ptolemaic law see M.-Th. Lenger, *Corpus des ordonnances des Ptolémées* (Acad. Roy., Brussels, 1964); many of the important documents concerned with Roman law appear in V. Arangio-Ruiz, *Fontes Iuris Romani Anteiusiniani*, Vol. 3 (Barbéra, Florence, 1943). The trial of Hermias and the Priests is found in U. Wilcken, *Urkunden der Ptolemäerzeit* (de Gruyter, Leipzig, 1927–1957). The Gnomon of the Idios Logos is in *Aegyptische Urkunden aus den Staatlichen Museen zu Berlin, Griechische Urkunden*, Vol. 5, W. Schubart and W. Graf Uxkull-Gyllenband, eds. (Staat. Mus., Berlin, 1919–1934). The replies of Severus are in *Apokrimata*, W.L. Westermann and A.A. Schiller, eds. (Columbia, New York, 1956). Menches' papyri are in *The Tebtunis Papyri*, Vol. 1 (E.E.S., London, 1902), those of Petaus in *Das Archiv von Petaus*, U. Hagedorn, D. Hagedorn, L.C. Youtie, and H.C. Youtie, eds. (Westdeutscher Verlag, Cologne/Opladen, 1969). A.C. Johnson, *Roman Egypt*, in T. Frank et al., *An Economic Survey of Ancient Rome* (Hopkins, Baltimore, 1936), gives a mass of documents in translation with commentary. More recent sourcebooks include J. Rowlandson, ed., *Women and Society in Greek and Roman Egypt* (Cambridge U.P., Cambridge, 1998); R.S. Bagnall and P.S.

Derow, *The Hellenistic Period* (Historical Sources in Translation; Blackwell, Oxford, 2004); and R.S. Bagnall and R. Cribiore, *Women's Letters from Ancient Egypt, 300 BC-AD 800* (Univ. of Michigan, Ann Arbor, 2006). For schools, see R. Cribiore, *Gymnastics of the Mind: Greek Education in Hellenistic and Roman Egypt* (Princeton U.P., 2001).

10. Language: The Duke Databank of Documentary Papyri provides a full-text database of the documentary Greek papyri. A CD-ROM version up to 1995 was published by the Packard Humanities Institute; an online version with more recently published texts is available at <http://www.papyri.info>. The lexicon of the papyri is F. Preisigke et al., *Wörterbuch der griechischen Papyrusurkunden* (Author, 1924): Vols. 1–2, dictionary; Vol. 3, special lists of kings, officials, taxes, etc.; Vol. 4, a supplement in form of dictionary, 5 fascicles to date. Three Supplements (1969–2000) give references only for texts from 1941 to 1988. For later publications, the online *Wörterlisten*. Available at <http://www.zaw.uni-heidelberg.de/hps/pap/WL/WL.html> may be consulted. For personal names, F. Preisigke, *Namenbuch* (Author, Heidelberg, 1922); and D. Foraboschi, *Onomasticon Alterum Papyrologicum* (Cisalpine, Milan, 1967–1971). E. Mayser, *Grammatik der griechischen Papyri der Ptolemäerzeit* (de Gruyter, Berlin/Leipzig, 1906, 2 vols., in several parts) is the standard work on grammar, but he does not treat the Roman papyri. A treatment of phonology and morphology of papyri of Roman and Byzantine times is given by F.T. Gignac, *A Grammar of the Greek Papyri of the Roman and Byzantine Periods*, 2 vols. (Cisalpine, Milan, 1976–1981).
11. Conclusion: Besides works cited above, note the general introduction to the field and selection of texts in the fundamental work of U. Wilcken and L. Mitteis, *Grundzüge und Chrestomathie der Papyrskunde* (Teubner, Leipzig, 1912, 4 vols.). A selection of documents is translated in the Loeb Classical Library *Select Papyri* (Heinemann, London, 1932–1934, 2 vols.), by C.C. Edgar and A.S. Hunt; a volume of literary papyri (poetry only) by D.L. Page (Heinemann, London, 1941) has also appeared.

Patents and Patent Searching

Michael J. White

Engineering and Science Library, Queen's University, Kingston, Ontario, Canada

Abstract

Patents are limited monopoly rights granted by governments that allow inventors to prevent others from making, using, or selling their inventions for up to 20 years. In exchange, inventors must disclose details about their inventions. Patent documents are a valuable open source of scientific and technical information, some of which does not appear in other types of publications. For more than 200 years patent offices have disseminated patent information to the public in order to promote awareness of patent rights and to further technological development. During that time patent documents have evolved from handwritten manuscripts to printed documents to electronic text. Print-based search tools such as indexes and patent classification manuals have given way to online databases and hyperlinked documents. Today, patent searchers can search and retrieve millions of patent documents from numerous free Web-based databases hosted by patent offices and independent organizations.

PATENT INFORMATION

Patent literature is one of the oldest and most interesting forms of technical literature in the universe of sci-tech information. Patents first appeared in Europe in the fifteenth century as a special privilege granted by monarchs. The World Intellectual Property Organization (WIPO) predicts that in 2008 more than 2 million patent applications will be filed and 750,000 patents granted worldwide. China, Japan, and the United States are the countries with the highest growth.^[1]

Simply stated, a patent is a monopoly right granted by a government to an inventor for a limited time, generally 20 years, that allows the inventor to exclude others from making, using, or selling his or her invention. Modern patent law is based in part on the concept of novelty. That is to say, in order to obtain a patent, an inventor must prove that his or her invention has never before been published, used, or sold in public. This requirement is not limited by geography or time. The inventor must also fully disclose the nature of the invention he wishes to protect. This exchange of information for monopoly rights is at the heart of the patent system.

Of course, patent information is most useful to patent owners and inventors wishing to apply for patent protection. It is always a good idea to conduct a patentability search before applying for a patent. Patents are also a valuable source of business information and competitive intelligence.^[2,3]

Patents are an important source of historical information about technological development, geographic regions, culture, and social trends.^[4-6] Patent documents can be used for genealogical research or to identify the date of an antique. Patents can be used to teach students at all levels

about science, engineering, inventiveness, and problem solving.^[7,8] Patents are an important source of technical information that is not published in scientific journals.^[9,10] Increasingly, patent information is a window into industrial and academic research conducted in developing countries.

In order to understand patent information and patent searching, it is necessary to understand how patent information and search tools and techniques have evolved over the last 200 years.

HISTORY OF PATENT INFORMATION

1790–1870: Early Beginnings

Prior to the 1870s, patent information was difficult, costly, and at times impossible for the average citizen to obtain. Printing was expensive, communications were slow and public access to government documents limited. In many countries, patent laws were administered in a haphazard and decentralized fashion. For example, in the United Kingdom prior to 1852, patents were registered by three separate offices located in England, Scotland, and Ireland. In North America, colonial assemblies granted their own patents, a practice that was continued by U.S. state legislatures after the American Revolution. In Canada, the patent office moved no fewer than six times from 1824 to 1857 as the colonial capital moved to Kingston, Montreal, Toronto and, finally, Ottawa.

In the United States, the Patent Act of 1790, the first federal patent statute, provided no means for printing patent documents or publishing information about granted patents.^[11] It did, however, authorize the secretary of state, who was responsible for administering patent

records, to provide copies of specifications upon request for a small fee. In 1791, Secretary of State Thomas Jefferson proposed patent reform legislation that would require inventors to publish information about their patents in federal district court gazettes. Furthermore, Jefferson proposed that copies of patents, printed at the government's expense, be made available to the public upon the expiration of the 14 year patent term.^[12] However, no such provisions were included in the Patent Act of 1793, although it did allow the public to request copies of patents at the rate of 20¢ per 100 words and \$2 for drawings.^[13] Patent applications were confidential and, therefore, not permitted to be copied.

The Patent Act of 1793 was in force until 1836. During most of this time the patent system was administered by one man, Dr. William Thornton, who served as the superintendent of patents from 1802 until his death in March 1828. Thornton understood and appreciated the value of patents as records of scientific progress and human ingenuity. When the British captured Washington, D.C. during the War of 1812, Thornton's appeals to the officer in charge of burning government buildings saved the Patent Office from being put to the torch.^[14]

Having saved patents for posterity, Thornton, however, was less enthusiastic about providing copies of patents to his fellow citizens. He frequently rejected such requests on the grounds that he did not have the authority or resources to do so. The latter was certainly true. Burdened with an increasing workload and lacking sufficient staff, Thornton often enlisted his wife to help write out patents.^[15] Thornton also wanted to protect the patent rights of inventors, believing that easy access to patents would only encourage piracy. In 1825, the Franklin Institute of Philadelphia sued Thornton after he refused to provide copies of patents which it wanted to abstract in its journal. After a lengthy court battle, the matter eventually was put before Secretary of State Henry Clay (Thornton's boss), who decided that patents were indeed public documents.^[15]

The Patent Act of 1836 clarified and affirmed the public's right to access patent documents.^[16] It also reduced the fee for copying patents to 10¢ per 100 words. In order to meet the demand for patent copies, the Patent Office hired temporary employees, most of them women working in their own homes, to transcribe documents on a piecework basis. In the 1850s the Patent Office was the first government office to hire women as full-time clerks. Clara Barton, founder of the American Red Cross, worked as a patent copyist and clerk from 1855 to 1857 and 1860 to 1865.^[17] When printed patents reduced the need for copyists, women were employed in the production of patent documents and the *Official Gazette*.

On December 15, 1836, fire destroyed the Patent Office and all its records and models. After the smoke cleared, Congress quickly appropriated funds to restore the files.^[18] But of the approximately 10,000 patents issued

from 1790 through 1836, only about 2,700 were recovered. Of these, 70% issued after 1830, 23% issued from 1810 through 1830 and 7% prior to 1810. Only six of the 67 patents issued under the Act of 1793 exist today. Occasionally, persistent patent researchers discover copies of missing pre-1836 patents in libraries, archives, and courthouses.^[19]

The Patent Office Fire of 1836 was a huge disaster for patent information, but not everything was lost. Lists of patentees and patented inventions had been published from time to time by the Patent Office and private companies. For example, S. Alfred Elliott, a Washington, D.C. printer of directories and guidebooks, published a list of granted patents from 1790 forward, updated annually, throughout the 1820s. Other publishers soon took notice of the public's increasing interest in patent information. The *Scientific American*, a weekly periodical established in 1845 to chronicle developments in American science and technology, also published claims of newly issued patents. Prior to the establishment of the *Official Gazette of the Patent Office* in 1872, it was the only reliable and timely source of information on new patents. The Patent Office even purchased extra copies of each issue for the use of patent examiners and in the preparation of its annual reports.^[20]

Lists of granted patents were included in the superintendent of patent's annual report to Congress from 1810 forward; however, it was published regularly only after 1836. During the 1840s the annual report was expanded to include alphabetical and classified lists of expired patents, a classified list of issued patents, alphabetical list of patentees and the claims of issued patents, miscellaneous reports and statistics, and other information related to agriculture. The latter was discontinued in 1862 upon the creation of the Department of Agriculture. Latter years included patent drawings. During this period the annual report was printed in huge quantities; for example, 135,000 copies of the 1847 report were produced, the bulk of which was delivered to members of Congress.^[21] Two especially useful guides to early U.S. patent documents include *A List of Patents for Inventions and Designs, Issued by the United States from 1790 to 1847*^[22] and the three-volume *Subject Matter Index of Patents for Inventions Issued by the United States Patent Office from 1790 to 1873, Inclusive*.^[23]

1870–1970: The First Golden Age of Patent Information

Three developments in the early 1870s ushered in a golden age of patent information: the printing of patent specifications and drawings, the establishment of a weekly *Official Gazette* containing abstracts of issued patents, and the distribution of patents to public libraries. Advances in printing technology in the mid-1800s greatly reduced the cost of printing, making it feasible for the first time to produce

large quantities of patent documents quickly and relatively inexpensively. The invention of photolithographic printing in the 1850s revolutionized the reproduction of technical drawings. Previously, patent drawings had to be hand-drawn by a skilled draftsman or engraved on metal plates at great expense. Photolithography also allowed drawings to be reproduced in different scales without the loss of details. The adoption of wood pulp papermaking techniques in the 1870s and the invention of the linotype automatic printing press in the 1880s further decreased the cost of printed patents.

In 1861, Congress first authorized the printing of patent specifications and drawings, but very little progress was made toward this goal during the Civil War. In 1871, a new Patent Commissioner, General Mortimer D. Leggett, was appointed and Congress again directed that copies of patents be printed for sale to the public and free distribution to libraries. Commissioner Leggett undertook this task with energy and initiative. He ordered that copies of all patents, including patents recovered after the fire of 1836, be transcribed and printed. The weekly publication and distribution of new patents would continue for over a century. By the 1960s, the Patent Office had amassed an archive of 100 million printed patents stored in vaults beneath the Department of Commerce Building on Pennsylvania Avenue.^[24]

In 1870 the Patent Office began publishing a weekly pamphlet containing claims of issued patents. This publication evolved into the *Official Gazette of the United States Patent Office*, which officially debuted on January 3, 1872. The *Official Gazette*, or OG as it became known, contained one or more patent claims with a representative drawing for each patent, in addition to summaries of the Decisions of the Commissioner of Patents, Patent Office statistics, and official notices. The OG greatly expanded the distribution of patent information. The \$6 yearly subscription fee was affordable to most individuals and organizations. Numerous patent attorneys, inventors, libraries, and foreign patent offices subscribed. A week's worth of patents occupied a thin volume; an entire year could fit easily on a bookshelf. The publishers of the *Scientific American* enthusiastically proclaimed that the OG would end the need for costly patent examination and litigation, as every applicant could consult the OG prior to filing their application.^[25] The success of the OG inspired other countries to follow suite with their own patent journals. The *Canadian Patent Office Record* was first published in 1873. The British Patent Office established its *Official Journal (Patents)* in 1884.

The third development in the 1870s that greatly enhanced the public's access to patent information was the decision by Congress and the Commissioner of Patents to distribute copies of patents to libraries. The Patent Act of 1836 required the Patent Commissioner to grant the public access to the patent models and records stored in the Patent Office. About 20 libraries, mostly located in the

industrial cities of the northeast and midwest, were initially selected to receive copies of patents. This network of patent depository libraries would remain relatively stable until the mid-1970s when the U.S. Patent and Trademark Office (USPTO) launched a program to recruit more libraries into the program. There are currently 83 designated Patent and Trademark Depository Libraries (PTDL).^[26] Of course, many non-PTDL libraries can and do provide patent information to the public.^[27]

Patent information dissemination became international. The 1870s and 1880s was a time of increasing international trade and capital investment and closer cooperation among countries on matters related to intellectual property protection. In 1883, 10 countries, including France and the United Kingdom, signed the Paris Convention for the Protection of Industrial Property, the first international intellectual property agreement. Article 12 of the Convention requires member states to establish a central office for disseminating patents to the public and to publish an official periodical journal containing information on granted patents and registered trademarks. Although countries had exchanged patent documents as early as the 1850s, the Paris Convention set the first international standard for disseminating patent information.

The dissemination of patent information remained unchanged for 100 years. The Patent Office continued to print and distribute copies of patents for a small fee to individuals and designated patent depository libraries. Those who did not want or could not afford to purchase patent copies, could subscribe instead to the *Official Gazette*.

1970–2008: Patents Go Digital

The arrival of digital computers in the 1950s promised to revolutionize how patent information was produced, stored, searched, and disseminated. As early as 1950, the Patent Office had conducted pilot projects using IBM punch card machines to store and retrieve patent information.^[28] In 1955 the U.S. Patent Office established the Office of Research and Development (ORD) to study the possibility of developing mechanical and, later, hybrid mechanical–digital patent search systems.^[29] In 1962, the Patent Office joined with other national and regional patent offices in the International Committee for Information Retrieval among Examining Offices (ICIREPAT) to study the possibility of an international patent search system. During the 1960s, ORD tested a number of experimental patent search systems based on index cards, inverted files, and microforms.

Little progress was made in digital search systems until 1970 when the Patent Office awarded its first contract for transcribing the full text of allowed patent applications onto magnetic tape. The tapes were used on a Linotron machine at the Government Printing Office to compose patents for printing; the first patents printed from electronic text issued on August 4, 1970.^[30] Afterward, the

Patent Office retained the tapes to create a full-text patent database. In the meantime, the Patent Office continued to test and deploy computer-operated microfilm search and retrieval systems. In 1980 the USPTO started distributing to libraries copies of patents on microfilm, thus ending more than a century of paper distribution.

In September 1981, the Patent and Trademark Office awarded a contract to a private firm to develop and deploy to patent depository libraries a Classification and Search Support Information System (CASSIS). Using CASSIS, users could, among other things, search words in U.S. Patent Classification (USPC) class and subclass titles and display all patent numbers assigned to a specific subclass. CASSIS was the first online patent search system available to the public. In 1987, the USPTO established a pilot project to evaluate the potential for a CD-ROM-based patent search tool as a replacement for CASSIS. The project was a success and in 1989 the first CASSIS/CD-ROM discs were released to patent depository libraries. The CASSIS series expanded in the early 1990s to include CD-ROMs containing searchable patent bibliographic, classification and assignment data, and full-text patent manuals.^[31] In the mid-1990s, a second CD-ROM product called *USAPat* was released. *USAPat* contained the facsimile images of patent documents and by the end of the decade replaced patents on microfilm.

In the early 1980s, Congress ordered the USPTO to develop an in-house patent search system for patent examiners. The Automated Patent System (APS) was operational by the end of the decade. APS was a full-text database with powerful search functions. Beginning in 1991, APS was offered at select patent depository libraries. APS was replaced by the WEST and EAST search tools in 1999, which were extended to all patent depository libraries in 2003.

The development of the World Wide Web in the early 1990s ushered in a new age in the dissemination of patent information.^[32] In 1994, the USPTO in cooperation with the Center for Networked Information Discovery and Retrieval (CNIDR) mounted its first patent database on the Web, the International AIDS Patent Database, a full-text collection of European, Japanese, and U.S. patents related to AIDS/HIV. In November 1995, the USPTO released a database of bibliographic data from patents granted from January 1976 forward. By October 1, 2000, the USPTO patent database contained full-text patents from 1976 forward and images from 1790 forward. In March 2001, the USPTO launched a second database for published applications.

Other patent offices quickly followed suit with their own Internet patent databases. In addition, a number of free unofficial patent databases appeared in the late 1990s. First were the EDS Shadow Patent Office, which offered free browsing of the current 52 weeks of U.S. patent titles and numbers, and IBM Patent Search, a free database of U.S. patents from 1971 forward. EDS and IBM are no longer operational, but in their place have appeared Google Patents, Patent Lens, FreePatentsOnline, and others.

The rise of powerful computer technology and universal Internet access radically changed patent dissemination in a very short time. Most patent offices discontinued print gazettes. The print version of the USPTO OG was discontinued in 2002 in favor of Web-based and CD-ROM versions. In 2003, paper patent search files were removed from examiner work areas and the Public Search Facility. Also in 2003, the USPTO launched Public PAIR, an online repository for case files for published applications and issued patents.

Of course, these rapid changes also presented challenges. The patent information industry, which earned large sums from patent search tools and document delivery services, was angered by what it saw as unfair competition from the patent offices. Its representatives argued that patent offices were exceeding their mandates in providing free Internet access to patent data.^[33,34] At times the relationship between patent offices, which supply patent data, and patent information companies has become tense and confrontational.^[35] Although there has been some consolidation in the patent information industry since 2000, free patent databases have also inspired new products and services.

Librarians at patent depository libraries were also concerned that Internet patent databases might put them out of the patent information business.^[36,37] To date this has not happened. There are currently 83 patent depositories in the United States, four more than in 1995. And in Europe, the PATLIB network of patent information centers has expanded four more than 320 sites in 83 nations. Librarians at non-depository libraries, especially librarians at universities, may be working with patent information more in response to increasing interest among instructors and students.^[38]

PATENT DOCUMENTS

Historically speaking, patent offices have published patent documents in a variety of formats that reflect their own national customs, patent laws, and publication requirements. During the last few decades, however, the patent offices of the world, under the auspices of WIPO and various intergovernmental working groups, have established a number of standards governing the format of patent information in order to facilitate the exchange, storage, and use of electronic patent data. The international movement toward harmonization and increasing cooperation between patent offices has also led to greater standardization in patent documents.

Patent documents consist of three parts: the *front page*, *drawing*, and *specification*. The term *Letters Patent* refers to the grant, drawing, and specification. The *grant* is the certificate issued to the inventor. The *front page* contains bibliographic information describing the patent document and may also include an abstract, the name of a patent

attorney/agent, list of references, and/or representative drawing. Common bibliographic data include patent number, date of issue, publication number, date of publication, application number, date of application, name of inventor, name of applicant or assignee, patent classification, and title of invention.

The *drawing* consists of one or more pages of numbered figures that illustrate the invention. It may appear after the front page or at the end of the patent document. Patent offices have specific requirements on what constitutes an acceptable drawing. In general, drawings must be rendered in black and white and show enough detail to enable the reader to understand the invention. Color drawings and photographs are generally not acceptable, except for U.S. plant patents, and black and white photographs are only permitted in limited circumstances where black and white drawings would not adequately illustrate the invention. Drawings are not required in patent documents that describe a process or method of doing something, such as a method of synthesizing a new chemical compound.

The *specification*, which is also known as the description, contains a description of the invention. At the end of the specification are the claims. The specification may start with a description of the background of the invention and a discussion of the prior art related to it. The claims describe, in legal terms, the scope of the invention.

A patent document may be of any length ranging from a few to several hundred pages depending on the complexity of the claimed invention. A few exceptionally long patent documents have page counts in the thousands.

INID Codes

INID is an acronym that stands for “Internationally Agreed Numbers for the Identification of (bibliographic) Data.” INID codes, which are described in WIPO Standard ST.9, identify bibliographic data printed on the front page of a patent document. See the table below for selected INID codes. (see Table 1) INID codes are printed in circles or parentheses.^[39]

Table 1 Selected INID codes

10	Patent number
12	Type of document
21	Application number
22	Filing date
43	Issue date
45	Publication date
51	International Patent Classification
54	Title
57	Abstract
71	Applicant
72	Inventor
73	Assignee

Document Kind Codes

Document kind codes distinguish between types of published patent documents as defined under WIPO Standard ST.16.^[40] While most major patent offices began including kind codes on their patent documents in the 1970s and 1980s, the USPTO began doing so only recently on January 2, 2001. (see Table 2) Kind codes are usually printed near the patent or published application number on the front page of a patent document and may be enclosed in a circle or parentheses. In general, kind codes A, B, and C are used on documents related to patent applications; P for plant patents (US); S for design patents (US); T for translations; and U, Y, and Z for utility models.

Utility Patents

Utility patents protect new and useful processes, machines, products, and compositions of matter or improvements of any of the above. The type of subject matter eligible for patent protection may differ from country to country. For example, patent protection for some applications of computer software, medical therapies, and genetically modified living organisms is allowed in the United States but not in many other countries. Some countries severely restrict patents for pharmaceuticals and medical treatments. Inventions deemed harmful to public safety and national security may be denied patent protection. For example, inventions that facilitate criminal or immoral activity, e.g., a letter bomb, cannot be patented in most countries. In the United States, the Atomic Energy Act of 1954 specifically prohibits the patenting of inventions related to nuclear weapons.

In most countries, utility patent applications are published 18 months after filing. The United States adopted 18 month publication only in 2001. The term of a utility patent is 20 years from the date of application and

Table 2 Kind codes applied to U.S. patent documents as of January 2, 2001

Code	Document type
A1	Utility application, first publication
A2	Utility application, second or subsequent publication
A9	Utility application, correction
B1	Utility patent, no pregrant publication
B2	Utility patent, with pregrant publication
C	Reexamination certificate (C1, C2, C3, etc.)
E	Reissue patent
H	Statutory invention registration
P1	Plant patent application, first publication
P2	Plant patent, no pregrant publication
P3	Plant patent, with pregrant publication
P4	Plant patent application, second or subsequent publication
P9	Plant patent application, correction
S	Design patent

most countries require the payment of maintenance fees during the life of a patent. About 7.5 million patents have been granted in the United States since 1790; 1.9 million utility and plant patent applications have been published since 2001.

Since 1995, applicants have been able to file in the United States a provisional application for a plant or utility patent. Provisional applications are not examined and applicants have one year from the date of filing to file a regular, or non-provisional, application based on their provisional. The requirements for a provisional application include a written description and drawing, if necessary to understand the invention. Provisional applications are not published but are included in the file wrapper of any subsequently filed non-provisional application.

Utility Models

Utility models are a weaker form of protection for innovations that do not meet the criteria for a patent. They are granted in a few countries, including Australia, China, Germany, Japan, and Mexico. Application fees are less expensive and the examination process is much less rigorous than for patents. The term of a utility model is much shorter than a patent, generally 5–10 years. Utility model applications may be assigned International Patent Classification (IPC) codes.

Design Patents

Design patents, or industrial designs as they are known in some countries, protect new, original, and ornamental designs applied to a product. For example, the ornamental design of a lamp or the shape of a food storage container may qualify for design patent protection. In the U.S. design patents have a term of 14 years from the date of issue. In Canada, the term for industrial designs is 10 years. Design patents were first granted in 1842 in the U.S. and in 1849 in Canada. The specification of a design patent is short, generally limited to a brief description and one claim. As of July 2008, approximately 560,000 design patents have been granted in the U.S. The WIPO-administered Hague System for the International Registration of Industrial Designs provides for the international registration of designs. The U.S. and Canada are not members of the Hague System. The Locarno Classification system provides for the classification of designs; approximately 49 countries, including the U.S. but not Canada, apply Locarno classifications to their industrial designs.

Plant Patents

Plant patents are unique to the U.S. They were established in 1930 for the protection of distinct and new varieties of asexually propagated plants, which includes plants that are reproduced by means other than seeds. Like utility patent

applications, plant patent applications are published 18 months after filing. The first plant patent was granted in 1931. The term of a plant patent is 20 years from the date of filing and maintenance fees must be paid as for utility patents. Plant patent specifications must provide a complete description of the plant but only one claim is allowed. Where color is a distinctive feature of a plant, color drawings or photographs must be provided. Plant patents are classified in the USPC in Class PLT. As of July 2008, approximately 18,000 plant patents have been granted.

Reissue Patents

An inventor who has claimed less than he or she is entitled to in a patent may apply for a reissue patent. Reissue patent applications are examined like regular patents. The term of a reissue patent does not extend beyond the term of the original issued patent. The first reissue patent was granted in 1838 and about 39,000 reissue patents have been granted since.

Additional Improvement (AI) Patents

The Patent Act of 1836 permitted inventors to apply for AIs to their patented inventions within 2 years of issue. From 1837 through 1861 the Patent Office granted approximately 300 AIs.^[41] AI patents were assigned a unique serial number for identification purposes but were considered integral to the original patent specification. The Patent Act of 1861 abolished AI patents and instead required inventors to obtain separate patents for subsequent improvements. AI patents are included in the USPTO database and may be retrieved by number, date of issue, and current classification.

Defensive Publications and Statutory Invention Registrations (SIRs)

In 1968 the USPTO enacted a new rule permitting applicants to request publication of unexamined patent applications. The intent of the rule, which was known as defensive publication, was to give applicants a means of protecting their inventions when obtaining a patent was not practicable. Defensive publication documents include only bibliographic information and an abstract. The entire application may be obtained by requesting the appropriate file from the USPTO. Defensive publications are identified by a unique number consisting of the prefix T (for technical disclosure) followed by the *Official Gazette* volume number and a serial number ranging from 1 to 999. Approximately 5,000 defensive publications were published from May 1, 1968 through July 5, 1988.

In 1985 defensive publications were replaced by statutory invention registrations (SIRs). SIRs never exceeded 200 in any given year and have steadily decreased in

number since 2001 when the USPTO began publishing utility and plant patent applications.

Reexamination Certificates

Reexamination certificates are issued upon completion of a reexamination proceeding. Reexamination proceedings were introduced in 1980 as a means of allowing third parties to challenge the validity of claims in a granted patent based on new prior art. Approximately 9,300 reexamination certificates have been issued since 1981. Reexamination certificates are attached to the original patent and can only be retrieved in the USPTO's Web-based patent databases by searching the appropriate document number.

Certificates of Correction, Disclaimers, and Dedications

The USPTO does not republish patents that contain minor typographical errors. Instead, the USPTO may at the request of the patent owner issue a certificate of correction that contains the corrected material. A copy of the certificate is then attached to the original patent. Certificates of correction have been issued since the late 1800s. (See patent no. 200,709.) Lists of patent numbers that have been issued certificates of correction are published weekly in the *Official Gazette*. In recent years, it is not uncommon for the USPTO to issue several hundred certificates of correction in any given week. The USPTO publishes data on the number of issued certificates of correction in its annual report. Since 2003, the USPTO has issued approximately 137,000 certificates of correction.

A disclaimer is formal statement made by the applicant or owner of a patent that disavows one or more claims in an issued patent or allowed application that have been found to be invalid. A patent owner may also file a terminal disclaimer that dedicates to the public the entire term or any part of the term of a patent or allowed application.

The Certificate of Correction Branch in the Office of Patent Publication is responsible for issuing certificates of corrections and disclaimers. Electronic copies of certificates of correction and disclaimers may be accessed in the USPTO's Patent Application Information Retrieval (PAIR) system and PatFT patent database (but they are not searchable) several weeks prior to their publication in the *Official Gazette*.

Trial Voluntary Protest Program (TVPP) Publications

In the mid-1970s, the PTO conducted two trial voluntary protest programs (TVPP) to assess the effectiveness of allowing the public to comment on pending patent applications. The intent was to elicit from the public prior art

information not cited by the examiner which could impact the patentability of the claims. About 650 applications were partially published (abstract, drawing, and cited references). These documents were designated with a B prefix before the application serial number. The PTO concluded that TVPP was not effective and plans for a permanent program were abandoned.^[42]

Alien Property Custodian (APC) Documents

During World War II the U.S. government seized approximately 4,700 patent applications assigned to nationals of enemy and enemy-occupied countries. The Office of the Alien Property Custodian, the agency responsible for managing seized property, published the applications in order to promote their use by American industry.^[43,44] These documents became known as APC documents; they are identified by the prefix "APC" followed by the application serial number and date of publication. APC documents are not included in the USPTO patent database.

PATENT CLASSIFICATION SYSTEMS

Patent offices created patent classification systems to organize patent documents and, in some cases, non-patent literature (NPL) into searchable collections based on related subject matter. The two principal patent classification systems in use today are the USPC, which is used by the USPTO, and the IPC, which is used by more than 100 countries worldwide. Many countries that once maintained their own national patent classification systems have in recent years switched to the IPC. For example, the Canadian Intellectual Property Office phased out the Canadian Patent Classification (CPC) in the early 1990s and the U.K. Patent Classification, which was established in 1888, was discontinued in July 2007. The IPC has inspired two regional versions, the European Classification (ECLA) system used by the European Patent Office (EPO) and the File Index (FI) system used by the Japan Patent Office (JPO). These will be discussed in the context of the IPC.

USPC

The USPC was officially established in 1898, although its origins can be traced back to the 1870s.^[29] Originally consisting of some 200 classes, the USPC today consists of approximately 450 classes and 150,000 subclasses.^[45] The range of subject matter classified in the USPC is immense, ranging from apparel in Class 2 to genetically engineered animals in Class 800. It also includes one class for plant patents (PLT) and 33 classes for design patents (D1-D30, D32, D34, and D99). In this respect, the USPC is unique: no other patent classification system in use today encompasses inventions, designs, and plants.

The USPC also includes seven cross-reference art collection classes for subject matter that falls into multiple classes.

USPC classes are organized under one of four principals: 1) Industry or Use; 2) Proximate Function; 3) Effect or Product; and 4) Structure. An excellent starting point for learning about the USPC is *The Examiner's Handbook to the U.S. Patent Classification System*.^[46]

The USPTO assigns patent classifications to utility, design, plant and reissue patents, published utility and plant applications, SIRs, and defensive publications. Between 1979 and 1995, the USPTO classified foreign patents in the USPC.

The base unit of the USPC is the class/subclass, which is often referred to as a classification code, classification symbol or, simply, a classification. Each class/subclass pair is a unique identifier. For example, the classification "482/140" represents "Class 482, Exercise Devices," and "subclass 140, Sit Up Device." The USPC is a flat taxonomy. That is to say, classes are arranged in numerical order and not by subject matter. In a few cases one class has been expanded to multiple classes in order to accommodate an exceptionally large amount of subject matter. For example, classes 600, 601, 602, 604, 606, and 607 are considered to be integral to Class 128, Surgery.

The principal document of the USPC is the *Manual of Classification*, which includes class schedules for all 450 classes. A class schedule is a listing of all subclasses arranged as a hierarchy. The *Manual of Classification* is supported by *Index to the U.S. Patent Classification System*, an alphabetical listing of common terms and trademarks corresponding to individual classifications. Users can consult the *Index to the USPC* in order to determine their initial classification. Definitions are provided for all utility and plant subclasses and most design subclasses.

Revisions to the USPC are handled by reclassification projects, the end product being a classification order. Classification orders contain information on abolished and established classes and subclasses, indent changes, position changes, title changes, and changes to the definitions and USPC-IPC concordance. Orders are issued on the first Tuesday of every month. Since 1947 there have been approximately 1886 classification orders. Classification orders issued since November 2003 are available in PDF format on the USPTO Web site. In addition, a *Classification Orders Index*, which is updated quarterly on the USPTO Web site, contains all changes to the USPC from 1976 forward.

IPC

The IPC is administered by the WIPO in consultation with a Committee of Experts representing members of the Strasbourg Agreement. More than 100 countries apply

Table 3 IPC hierarchy

Section	A	Human necessities
Class	A62	Life saving, fire-fighting
Subclass	A62C	Fire-fighting
Group	A62C 11/00	Portable extinguishers with manually operated pumps

IPC codes to their patent documents. It is estimated that almost 95% of the 2 million patent documents published annually are assigned IPC codes. The United States began using the IPC in 1969 and Canada in 1978. The IPC is a hierarchical system that is divided into four subdivisions: sections, classes, subclasses, and groups. (see Table 3) There are 70,000 groups, of which 10% are main groups and the rest subgroups. Each subdivision is identified by a unique code and title. The eight top-level sections are identified by letter codes ranging from A, Human Necessities, through H, Electricity.

In January 2006, a new reformed version, the 8th edition, of the IPC was implemented. Prior to 2006, the IPC was revised and updated every 5 years. The 7th edition was in force from January 1, 2001 to January 1, 2005. The 8th edition is divided into two levels, the core and the advanced. The core level contains 18,000 classifications and is intended for use by smaller patent offices that issue fewer patents. Revisions to the core level occur every three years. The advanced level contains the full 70,000 classifications. Changes to the advanced level are made quarterly.

The EPO maintains the European Classification (ECLA), an extension of the IPC that includes, about 134,000 groups. ECLA's structure is very similar to IPC. In fact, many of the classifications are identical to corresponding IPC codes. For example, A01M 23/10 is the code for animal traps with rotating turnstiles or cylinders in both IPC and ECLA. The EPO classifies documents that are published in English, French, and German, German utility models, and documents published by Belgium, the Netherlands, and Luxembourg. About 30 million documents in esp@cenet have ECLA codes. ECLA is updated on an ongoing basis.

The JPO also maintains a version of the IPC called FI. Like ECLA, the FI is more detailed than the IPC.

PUBLIC PATENT DATABASES ON THE INTERNET

An in-depth discussion of all the public patent databases and search tools available on the Internet is beyond the scope of this entry. Therefore, only the most important resources will be discussed. The proliferation of Web-based public patent databases in the last decade has been both a boon and a challenge for public access to patent information. The public now enjoys better access to

patents than at any other time in history. Anyone with a laptop computer and a connection to the Internet can search dozens of free or semifree patent databases (from both patent offices and independent organizations) containing millions of patent documents. However, this wealth of information may also confuse and mislead novice searchers. When considering which patent database to use, the patent searcher must balance functionality and ease-of-use with currency and comprehensiveness.

CIPO

The CIPO launched its Canadian Patents Database (CPD) in October 1998. Today, the database includes patent bibliographic data from 1869 to the present and full-text data for abstracts and claims from August 15, 1978 forward. Images of patent documents in PDF and GIF formats are available for patents issued from January 1, 1920 to the present and laid-open applications published from October 1, 1989 to the present. As of July 2008, the database contains approximately 1.9 million records. It is updated weekly. As Canada has two official languages, English and French, patent applications may be written in either.

Since its launch, the CPD has undergone numerous improvements and enhancements. In August 2003 administrative status data became available for withdrawn applications and patents that have been reissued, reexamined, or expired. Maintenance fee payments and status data was added in April 2004. In May 2006 bibliographic data for patents issued from 1869 to 1920 was added. Searchable fields include title, abstract, claims, inventor, owner, applicant, Patent Cooperation Treaty (PCT) filing number, international publication number, and IPC and Canadian Patent Classification (CPC) codes. The CPC was discontinued in the early 1990s and is not included on patent documents published after this time.

USPTO

The USPTO Web site hosts four significant patent information systems: two patent document databases, a patent assignment database, and a patent application file search system. Additional patent status information is also published in the front sections of the *Official Gazette* which is available on the USPTO Web site from 1995 to the present.

USPTO Patent Databases

The Patent Full-Text and Image Database (PatFT) is one of the largest and oldest public patent databases on the Internet. It can trace its history back to November 1995 when the USPTO launched PatBib, its first comprehensive Internet-based patent database containing bibliographic data for patents issued from 1986 through 1995. The USPTO maintained a small database of AIDS-related patents from December 1994 through April 1999. PatBib was expanded

a few months later to include bibliographic data from January 1976 forward. Full-text data was added in November 1998, followed in March 1999 by images of patent documents in TIFF format. In October 2000, the USPTO again expanded PatFT by adding number and current classification data and TIFF images for patents back to 1790. Also in 2000, the USPTO added an integrated patent classification search tool that allowed searchers to retrieve patents in any given subclass. In April 2006, the date of issue for all patents from 1790 through 1975 was added.

PatFT currently contains data and images for approximately 8 million issued patents and related documents. It is updated every Tuesday when new patents are issued. Patent classification data for all patents is updated approximately bimonthly. In addition to searching full-text, users may also search separate fields including title, abstract, name of inventor, name of assignee, date of issue, patent number, date of application, application number, current classification, etc. Patents issued from 1790 through 1975 may only be retrieved by number, date of issue, and current classification. Certificates of correction, disclaimers, and dedications are not searchable, but are attached to the end of the patent document image.

In early 2001, the USPTO launched a second database called AppFT containing full-text data and images of published utility and plant patent applications, which are also known as pregrant publications. Since November 1999, all utility and plant patent applications have been eligible for publication 18 months after their effective filing date. The first pregrant publication was published on March 15, 2001. Searchable fields include many found in PatFT and Kind Code, etc. AppFT is updated on Thursdays when new applications are published. AppFT currently contains full-text data and images for approximately two million pregrant publications.

USPTO Assignment Database

Assignments on the Web, launched in December 2003, consists of two databases, one for patent assignments and one for trademark assignments. The Patent Assignment database contains all recorded assignment information for patents and published applications from August 1980 to the present; data is updated daily. Assignment records are searchable by patent number, publication number, assignor name, assignee name, and microfilm reel/frame number. Assignment records display the title of the patent, inventors' (assignor) names, assignee name, application number, date of application, date of execution, and date of recordation. Assignment records are linked to the PAIR system.

PAIR

The USPTO launched the PAIR system in mid-2003 using software acquired from the EPO. The system is divided

into two components: Private PAIR and Public PAIR. Private PAIR provides secure access to current patent application status. Only registered patent attorneys/agents, independent inventors, and persons granted limited recognition who have a valid USPTO customer number and digital public key infrastructure (PKI) certificate may access Private PAIR.

Public PAIR, which may be accessed by anyone, contains application bibliographic data for patents and published applications from about 1989 to the present. The system has very limited search capabilities. PAIR records may be retrieved by application number, patent number, publication number, PCT, application number, and control number (for *ex parte* and *inter partes* reexamination proceedings). In addition to application data, PAIR contains transaction history, patent term extension history, maintenance fee payments, applicant address, patent attorney/agent, parent/child application data and supplemental content, such as computer program listings and nucleotide/amino acid sequences.

PAIR also provides access to application file wrapper documents in PDF format for applications pending on or filed after June 30, 2003. File wrapper contents include all correspondence between the USPTO and applicant, application worksheets, copies of cited foreign patent documents, examiner search strategies, information disclosure statements, related provisional patent applications, etc. Copies of cited NPL, such as journal articles, are not available due to copyright restrictions.

The USPTO does not disclose the current number of file wrappers available in Public PAIR, but 1.5 million is a plausible estimate. In the first year after the launch of PAIR the USPTO digitized more than half a million pending applications. Since July 2003, the USPTO has published approximately 1.2 million applications and issued some 762,000 patents.

EPO

The EPO's public patent database is esp@cenet. Launched in 1998, esp@cenet contains more than 60 million patent documents, including utility models, from approximately 70 countries and 1 million references to NPL.^[47] The data is current for most patent offices. Patent documents are stored in PDF format and may be printed one page at a time. Documents with fewer than 100 pages may be downloaded and printed. Up to 100 documents may be stored in the My Patents list. Machine translation is available for several languages including German, Spanish, and French.

Documents may be retrieved by application, publication, or priority number, or NPL reference number. The Advanced Search allows users to search terms in the title, title and abstract, inventor and applicant, publication date, European Classification, and IPC. No date range search is available, but up to 4 years may be entered into the

publication date field in order to limit a search. Searches may also be limited by country by entering up to four country codes in the publication number field, e.g., CA, US, WO. Search results are displayed in accession order and may not be re-sorted.

Individual patent records are linked to INPADOC legal status and patent family data, and citing references. Cited references are provided for WO and EP documents.

Register Plus is the EPO's equivalent of the USPTO's PAIR system. It contains bibliographic and procedural data for published EP applications and international applications in which the EPO or one or more of its member states are designated. Legal status is available only for published EP applications. Patent family information is also available. One of the most useful features of Register Plus is that it provides access to all documents in an EP application case history, also known as a file wrapper. Users may retrieve documents by application or publication numbers, date of filing, date of publication, priority number, priority date, inventor, applicant, representative, opponent, and IPC classification. Users may register with the WebRegMT e-mail alert service to monitor changes in the status of EP applications; up to 1000 applications may be monitored per e-mail address.

The EPO's third free patent database is ESPACE EP, which was launched in May 2008. Unlike esp@cent and Register Plus, users must register with the EPO in order to access the system. ESPACE EP runs on MIMOSA, a powerful full-text search engine. Users may search the most recent 4 weeks of EP published applications and patents. Users may also customize display, printing, and download options.

JPO

The JPO's Intellectual Property Digital Library (IPDL) contains Japanese patent and utility model data and images from 1922 to the present. IPDL offers several access points. Users may retrieve documents from the Patent and Utility Model Gazette Database by kind code and document number. Prior to January 2000, Japanese patent and utility model documents numbers were prefixed by the imperial year. For example, H12-123456, is the number of a document that was published in the 12th year (2000) of the reign of Emperor Akihito (1989-), also known as the Heisei period. After January 2000, the JPO adopted western years, e.g., 2000-123456, as prefixes.

Users may search the *Patent Abstracts of Japan* (PAJ) by document number, word in the title, applicant or abstract fields, date of publication, and IPC code. PAJ contains data from 1976 forward and is updated monthly. Utility models are not included in PAJ. Recent documents are automatically machine translated into English. PAJ contains legal status data from January 1990 forward; it is

updated biweekly. Users may also conduct an FI/F-term classification search or browse the FI/F-term system using the Patent Map Guidance. An FI/F-term search will retrieve patents and utilities models back to 1885. Users may limit an FI/F-term search by publication date range and document type.

WIPO

WIPO's PatentScope Web portal, which was launched in mid-2005, provides access to bibliographic and full-text data and document images for 1.3 million PCT international patent applications published from 1978 to the present. The database is updated weekly (usually on Thursdays) when new international applications are published. PatentScope is the successor to the WIPO's electronic *PCT Gazette*, which went online in October 1998. The print and digital versions of the *PCT Gazette* was discontinued in April 2006.

PatentScope supports more than 25 searchable fields, including title and abstract in English or French, applicant and inventor name, address and country of residence, publication, application and priority number, IPC code, etc. The language of filing and publication may be searched by the full name or abbreviation of the language, e.g., "German" or "DE." Approximately 650,000 PCT applications are available in English, German 139,000, and Japanese 130,000.

PatentScope supports a number of advanced features not found in other patent office databases. Users may register for a free account where they can store search queries in between sessions. Search results may be sorted by date or relevance and search result displays customized. In late 2006, WIPO added RSS feeds for updated searches and graphical views of search results. Users may generate graphs displaying search results by year of publication, country of publication, applicant name, and IPC code.

The WIPO Web site also hosts the Hague Express Database of internationally registered industrial designs. Records are searchable by registration number, owner, international registration date, Locarno classification, indication of products, priority date, publication date, and contracting parties. No information is provided on coverage and update frequency.

FreePatentsOnline

FreePatentsOnline is a free patent database supported in part by paid advertising. Since its launch in 2004 it has become one of the more popular independent patent databases on the Internet. It contains searchable full-text patent documents from the United States (1976–), Europe (1978–), WIPO/PCT (1978–), and Japanese abstracts from 1976 forward. PDF images of U.S. patent documents are available from 1790 forward. Data and images for U.S.

withdrawn patents are available back to the mid-1980s. Certificates of correction and reexamination certificates are attached to the original patent.

There are 26 searchable fields, many of which are identical to the search fields found in the USPTO patent database. The Advanced Search mode allows complicated search queries using field codes, Boolean operators, proximity operators, term weighing and wildcards. Users who register for a free account may store up to 10,000 records in 20 folders. Saved references (up to 250 at a time) may be downloaded in spreadsheet format. Citations may be exported in BibTex and EndNote formats. Other tools include a Google Toolbar plugin and RSS feeds for new patents and published applications organized by category or USPC class.

FreePatentsOnline recently introduced a chemical structure search based on SureChem's normalized database of chemical names and structures. It is the first free patent database to offer chemical structure searching. Chemical structure, substructure, and similarity searches may be searched using SMILES (a chemical notation system that allows two-dimensional chemical structures to be represented by a linear string of characters) or a graphically drawn structure. Structure data is updated about week after new patents are published.

Google Patents

Google Patents was launched in June 2006. It contains OCR'd full text of U.S. patents and published applications from 1790 forward. It is not clear how frequently the data is updated, but the online FAQ indicates that coverage includes patents issued in the past few months. Documents are stored in PDF format and may be easily printed or downloaded. Certificates of correction and reexamination certificates are attached to the original patent.

The Advanced Search option allows users to search by patent number (but not by published application number), words in title, inventor name, assignee name, USPC code, and IPC code. Searches may be limited by document status (issued patent or published application), type of patent (utility, design, plant, etc.), issue date, and filing date. Search results are automatically ranked by relevancy and may be sorted by date. Records are linked to records in the USPTO patent database.

Google Patent's principal weaknesses are its lack of current USPC classification data and erratic classification search results. Its reliance on optical character recognition (OCR) full text also produces unreliable and erratic search results.

Patent Lens

Patent Lens, launched in early 2006, is the brainchild of a group of life science researchers in Australia who want to

make the patent system more transparent and patent searching easier for nonprofessionals. It contains almost 9 million full-text patent documents from Australia (1998–), the United States (1976–), Europe (1980–), and WIPO/PCT (1978–). Data is current for US, EP, and WIPO/PCT documents. AU documents may be several weeks behind.

Search modes include Quick, Structured, and Expert. Searchable fields include full-text, frontpage, title, abstract, inventor, assignee/applicant, agent, references, claims, and description. Expert search allows complicated search queries using field codes, Boolean operators, and wildcards. Searches may be limited by publication or filing date, and U.S. patent predicted expiry date and lapsed date. Patent documents may be saved and previous searches reused. Patent family and status data is provided where available. Patent families may be displayed as graphical trees in PDF format. RSS search alerts may be created.

Patent Lens is the only free patent database that supports gene sequence searching. It uses the National Center for Biotechnology Information's BLAST software to find DNA and protein sequences that are listed in U.S. patents and published applications.

The greatest disadvantage of the system is the inability to search current USPCs or IPCs. This is not an oversight. The designers of Patent Lens believe that patent classification is too complicated for their intended users. It is possible to do a crude approximation of a classification search by searching USPC or IPC codes in the frontpage. However, search results should be treated with caution.

People with Disabilities

Amelia Koford

Blumberg Memorial Library, Texas Lutheran University, Seguin, Texas, U.S.A.

Abstract

This entry discusses people with disabilities in relation to libraries and other information institutions. It briefly summarizes the social category of disability, the disability rights movement, relevant laws, and the history of disability in the literature and practice of information studies. It focuses largely on libraries, with some discussion of archives, museums, and for-profit information professions. The United States is the primary geographical focus, although other countries and international bodies are discussed. In addition to addressing accessibility of physical spaces, print resources, and electronic resources, the entry discusses disability as subject matter, library staff members with disabilities, and outreach. The entry emphasizes the importance of involving people with disabilities, both in scholarly research that concerns them and in accessibility evaluation and planning.

INTRODUCTION

Disability is a part of the human experience. Approximately 15% of people around the world have physical or cognitive impairments that limit their ability to perform one or more important functions.^[1] The interaction between these impairments and barriers in the environment is defined as disability.^[2] Disability is a category that anyone can enter as life circumstances change; some activists highlight this fact by referring to people without disabilities as “temporarily able-bodied.”^[3] People with disabilities are almost certainly present in any community served by libraries or other information institutions.

In recent decades, people with disabilities have made important gains in asserting their right to live, work, and play alongside others in their communities. Laws in many countries have affirmed the idea that social institutions and public spaces should be accessible to all. However, people with disabilities are still socially and economically marginalized. They face barriers to full participation in education, public life, and the workforce. Libraries, museums, websites, and other sources of organized information can be empowering resources for this underserved group; they also have the potential to contain barriers to access, reinforcing marginalization and isolation. Most information institutions contain a combination of enabling and disabling features. Information professionals need not wait until our institutions are perfect before cultivating relationships with the disability community.

Information professionals believe strongly in equity of access. The notion that resources should be available to everyone in a community is a core ethical principle of information professions. In practice, however, institutions often fall short of the accessibility ideal for a variety of reasons: finances, competing priorities for time and attention, attitudinal barriers, and lack of awareness. Many

dedicated information professionals have worked for decades to promote empowering and fair services for people with disabilities. In becoming allies with people with disabilities, information professionals enter a mutually beneficial relationship with a large, diverse sector of the community.

DISABILITY AS A SOCIAL CATEGORY

The meaning and scope of the category of disability varies among cultures and countries. A given set of physical or cognitive characteristics might be considered a disability in one context, but thought of as simple human variation in another context. Although the context-dependent nature of the term disability makes it difficult to quantify, the World Health Organization estimates that 15% of people worldwide have a disability.^[1]

The contemporary understanding of disability is that it is a social phenomenon. The social model of disability represents a shift from the previous conception of disability as an individual problem. Historically, the responsibility for disabled individuals' quality of life lay with the individuals and their families. Institutions that made accommodations for people with disabilities did so out of charity. In the second half of the twentieth century, due largely to activism and organizing by people with disabilities, a social model of disability emerged. The social model contests the idea that individuals and families should bear the burden of conforming to a nondisabled world. Under the social model, society is responsible for building its institutions in ways that include all citizens. The social model calls attention to the way that disability results from the interaction between a person's impairment and their environment.

There are many different kinds of disability. Some broad categories of disability are

- Mobility disabilities
- Sensory disabilities
- Cognitive disabilities
- Learning disabilities
- Mental illness

Many disabilities change in severity and expression over time. Some people experience multiple disabilities. Many disabilities are “invisible”; arthritis, epilepsy, learning disabilities, and many more are not apparent to an outside observer. In most cases, information professionals do not need to know the details of our users’ medical diagnoses; the important thing to understand what they need to effectively use information resources. In many cases, the best way to learn about what people need is to ask. A great deal of the current literature on accessibility of information institutions emphasizes the importance of consulting with people with disabilities.

The disability rights movement, which began after the end of WWII and continues today,^[3] focuses on the rights of disabled people to make their homes outside of institutions and to participate in all aspects of society. Some histories of the disability rights movement are Shapiro’s *No Pity: People with Disabilities Forging a New Civil Rights Movement*^[4] and Fleischer and Zames’s *The Disability Rights Movement: From Charity to Confrontation*.^[5] The academic field of disability studies, which is closely aligned with the disability rights movement, developed in the 1980s.^[6] The *Disability Studies Reader*, a good introduction to the field, is periodically updated with new editions.^[7] The major professional organization in the field is the Society for Disability Studies, which publishes the journal *Disability Studies Quarterly*.

Print Disabilities

The category of print disabilities is convenient when discussing disability in relation to libraries and information. Print disabilities are any disabilities that affect a person’s ability to read standard print and can include blindness, low vision, some learning disabilities, and some cognitive disabilities. The category includes people who have difficulty holding a book or turning pages. The term “print disabled” was coined by George Kerscher in the late 1980s.^[8] Ways for print-disabled people to access books and articles include magnification, change in font, text-to-speech technologies, audiobooks, and Braille.

Language

Among people with disabilities, as among many historically marginalized groups, language and labels are taken

seriously. Words are understood as vehicles for social power that can either enforce or subvert oppressive structures. Historically, people with disabilities have been given many labels, many of which strike the modern reader as dehumanizing: invalids, cripples, freaks, and the insane. In the 1980s, the people-first language movement grew out of a concern about the dehumanizing nature of much of the language used to describe people with disabilities.^[9] Advocates of people-first language promoted the use of words and phrases that emphasize the person rather than the disability. The American Psychology Association’s “Guidelines for Non-Handicapping Language in APA Journals”^[10] explains key principles of people-first language. Examples of preferred language include “blind people” rather than “the blind”; “people who have epilepsy” rather than “epileptics”; and “people with disabilities” rather than “disabled people.” Terms with superfluous negative overtones, like “a victim of...,” “afflicted by...,” or “confined to a wheelchair,” are discouraged.

Person-first language is not universally embraced; there is ongoing debate about it within the disability community. Especially in the United Kingdom, writers and activists tend to use “disabled people” rather than “people with disabilities.” Many in the autistic and blind communities also embrace identity-first language. Those who use identity-first language often view it as less linguistically cumbersome and as a way to assert their social and political identity (Schur et al.,^[11] p. 7). Both people-first and identify-first language are used in this encyclopedia entry.

In another example of the significance of language, many Deaf people capitalize the term to denote Deafness as a culture, while the term deafness with a lowercase “d” describes the physical condition. Hard-of-hearing is often used to describe the condition of partial hearing loss.^[12]

Some writers reject the term “hearing impaired”: Harlan Lane writes, “The label has embedded within it the infirmity model that legitimates that establishment; and it exists only in opposition to hearing; in this it is like ‘non-men’ as a label for women, ‘non-white’ as a label for people of color, or ‘sexually impaired’ as a label for gays” (Lane,^[13] p. 89). Others, in contrast, find “impairment” a useful term. Lennard Davis writes, “An impairment involves a loss or diminution of sight, hearing, mobility, mental ability, and so on. But an impairment only becomes a disability when the ambient society creates environments with barriers—affective, sensory, cognitive, or architectural” (Davis,^[14] p. 41).

As cataloging and metadata librarians are well aware, language norms are culturally relative and change over time. The most important policy for information professionals is to speak respectfully, be willing to ask people about their preferred language, and be open to changing language after receiving new information.

LEGISLATION

In 1990, the United States passed the Americans with Disabilities Act (ADA), a major piece of legislation addressing the civil rights of people with disabilities. Among other provisions, the ADA requires that employers make reasonable accommodations for workers with disabilities and that public buildings offer ramps, accessible parking, and accessible bathrooms. Several other countries also passed major civil rights legislation in the 1990s, including Australia (Disability Discrimination Act of 1992) and the United Kingdom (Disability Discrimination Act of 1995).

Another relevant law in the United States is the Rehabilitation Act, which prohibits discrimination on the basis of disability by the federal government. Section 508 of the Rehabilitation Act requires that websites and other information technologies used by the government be accessible to people with disabilities.

The United Nations Convention on the Rights of Persons with Disabilities, an international treaty obliging countries to protect the human rights of people with disabilities, was adopted by the UN General Assembly in 2006. As of this writing, 158 countries had signed the convention and 149 had ratified it. The United States is not among the countries that have ratified the convention.

NONLIBRARY INFORMATION INSTITUTIONS

While this entry focuses primarily on libraries, information needs and perspectives of people with disabilities are highly relevant to all information-focused institutions. Many of the entry's statements about libraries hold true for other types of institutions.

For-Profit Sector

Many information professionals are employed by for-profit companies, working in fields such as usability, information architecture, and database management. Accessibility of electronic resources is an important aspect of these fields. A 2007 special issue of the *Information Society* provides a multidisciplinary analysis of disability in information technology, addressing questions about how to align accessibility with the profitability goals of corporations.^[15]

Museums

In museum studies, there are ongoing conversations about ways to design exhibits with accessibility in mind. Strategies for enhancing the museum experience for disabled people include tactile exhibits, touch-tours, audio description of visual works, and closed captioning of audio

works. A 2013 special issue of *Disability Studies Quarterly* focuses on museum experience and blindness, featuring best practices, curators' perspectives, and personal accounts of museum experiences.^[16] Designing for accessibility can be a creative endeavor: Cachia, an art curator and chair of the Dwarf Artist Coalition of the Little People of America, calls on museums to "think about how access can move beyond a mere practical conundrum, often added as an afterthought once an exhibition has been installed, to use as a dynamic, critical and creative tool in art-making and curating" (Cachia,^[17] p. 259).

A few museums focus on disability as subject matter. The June 2014 issue of the *Journal of American History* features exhibition reviews of several brick-and-mortar museums: the Museum of disABILITY History in Buffalo, New York; the Oregon State Hospital Museum of Mental Health; and the Museum of the American Printing House for the Blind.^[18] Several online museums and exhibits document disability history. The Smithsonian's National Museum of American History hosts *EveryBody: An Artifact History of Disability in America*, which launched in 2013, as well as an ongoing web version of their 2000–2001 exhibit the Disability Rights Movement. The University of Leeds maintains the online Disability Archive UK. Another major online museum is the Disability History Museum maintained by Straight Ahead Pictures. Laurie Block, founder of the Disability History Museum, discussed the challenges of collecting and describing artifacts for the online museum in a 2007 article.^[19]

Representing disability in museums is complicated by historical traditions of exploitative, dehumanizing presentations of disabled bodies. Sandell, Delin, Dodd, and Gay discuss this topic in their article "In the Shadow of the Freakshow."^[20]

Archives

The archival record of disability experience, like the archival record for many historically disenfranchised groups, is fragmented. Some archives, such as the University of Toledo Archives, have proactively sought to find and preserve historical materials by partnering with community organizations.^[21] The Bancroft Library at the University of California, Berkeley, has a substantial collection of records from the disability rights and independent living movements. Articles in the archives literature have addressed finding aid accessibility^[22] and people with disabilities as archives employees.^[23]

HISTORY

Libraries began addressing the needs of people with disabilities long before the passage of the ADA. Throughout the 1960s, 1970s, and 1980s, a variety of books and

articles discussed library services for disabled patrons, particularly those with visual and mobility disabilities.

In the United States, the Boston Public Library established the first collection of embossed books for blind people in 1868, followed closely by the Library of Congress Reading Room for the Blind.^[24] In 1931, Congress passed the Pratt-Smoot Act (Act to Provide Books for the Blind), establishing what is now the National Library Service for the Blind and Physically Handicapped (NLS). The NLS produces Braille materials and audiobooks—also known as talking books—and distributes them by post-age-free mail to borrowers' homes. They recently began offering online access to talking books and Braille books (digital Braille books can be downloaded and printed using embossing hardware). The NLS operates through a national network of libraries in each state.

Before the independent living movement of the mid-twentieth century, many people with disabilities lived in institutions. A few authors have explored the histories of libraries patients' libraries in hospitals and mental institutions.^[25,26]

After the ADA was passed in 1990, many libraries made changes to come into compliance with its requirements for physical spaces. In a 1991 *American Libraries* article, Gunde describes efforts by the library profession to respond to the ADA. He describes brochures and conference programs sponsored by Association of Special and Cooperative Library Agencies (ASCLA). In colorful language, he calls on libraries to do more to make their programs and services inclusive: "Many citizens with disabilities will come to question the sincerity of our commitment to the professional principles that we so eloquently proclaim at our overcrowded conferences and in our bombastic Association resolutions" (Gunde,^[27] p. 809).

In 1994, Scheimann studied ADA compliance among Ohio public libraries.^[28] Although the study's scope is limited, it provides a useful glimpse into a point in time shortly after the passage of the ADA. Libraries reported relatively high levels of physical accessibility and provision of alternative formats—87% had accessible parking, 71% had appropriate aisle width, and 95% provided large print, for example. Most libraries had not solicited significant patron input—only 7% had done so, with some including patrons with disabilities on an ADA evaluation committee, some distributing evaluation forms, and one inviting members of the local Handicapped Society to tour the building and offer suggestions. Many libraries had neglected to perform the self-evaluation that public entities were legally mandated to perform in 1993. Survey respondents expressed concerns about the cost of modifications, and several stated a perception that their service community did not include people with disabilities.

Perry's 2014 study of information services for older adults showed that many, but not all, libraries were in compliance with ADA guidelines.^[29] Perry surveyed libraries in suburban counties, receiving 91 responses. Over 90%

of responding libraries provided large print and audiobooks, 87.9% of buildings met ADA guidelines, and 81.3% of library websites were ADA compliant. In a variety of other categories, including assistive technologies, large-print brochures, and visible and high-contrast signage, between 35% and 45% of libraries provided accommodations.

The ASCLA, a division of the American Library Association, has done substantial work promoting improved library services to people with disabilities. The ASCLA maintains a series of library accessibility tip sheets that provide brief, readable introductions to topics such as assistive technology, service animals, and various categories of disability.^[30] In 2001, the ASCLA was instrumental in adding a section on Library Services for People with Disabilities to the policy manual of the American Library Association.^[31]

The International Federation of Library Associations and Institutions (IFLA) is another long-time player in the field. What is now IFLA's section on Library Services to People with Special Needs was founded in 1931 as the Sub-Committee on Hospital Libraries. From 1981 to 2008, it was called the Section for Libraries Serving Disadvantaged Persons.^[32] During the section's long history, it has facilitated international cooperation among libraries serving people with disabilities and has published many sets of standards, guidelines, bibliographies, and resource lists. In 2005, it published the Access to Libraries for Persons with Disabilities Checklist, which is used internationally to evaluate and improve services.

In a content analysis of disability and accessibility in the library and information science literature from 2000 to 2010, Hill found a strong emphasis on accessibility of electronic resources and on visual disabilities.^[33] A comparatively small amount of research has focused on information behavior or on attitudinal and social barriers to access. Thirty-six percent of the research articles Hill examined involved participation by people with disabilities, and she states that increasing this proportion would benefit the field.

In the United Kingdom, the now-defunct Museums, Libraries, and Archives Council produced several tools and documents related to people with disabilities, including a database launched in 2005 of disability trainers and consultants with an interest in working with heritage organizations.^[34] The Museums, Libraries, and Archives Council was closed in May 2012 as part of government restructuring. Some of the Council's responsibilities were taken over by Arts Council England and the National Archives, but the Disability Experts database appears to no longer be maintained.

PHYSICAL RESOURCE ACCESSIBILITY

Space

Accessibility of physical spaces is an essential aspect of library services to people with disabilities. People who use

wheelchairs, walkers, or scooters need wide enough pathways to navigate library buildings. Some physical space considerations, such as signage, also affect people with visual and cognitive disabilities. The ADA mandates that any new construction or renovation of a public space follow accessibility standards. Institutions that do not follow these standards are open to lawsuits. The ADA Standards for Accessible Design were updated in 2010, replacing the 1991 Standards.

The practice of designing spaces to be inherently accessible to all, including elderly and disabled people, can be called universal design, accessible design, barrier-free design, or inclusive design. Universal design from the beginning of a project is easier than retrofitting non-accessible spaces, and it is more inclusive than making only certain areas accessible. William Sannwald's *Checklist of Library Building Design Considerations* includes a chapter on ADA considerations and is periodically updated to keep pace with current standards and technologies.^[35] Several libraries have successfully obtained grant or government funding for ADA compliance construction projects (Vincent,^[36] p. 51).

There are many ways for libraries to improve their physical accessibility without undergoing new construction or renovation. They can provide plenty of seating, good lighting, and large and high-contrast signs. They can make sure that aisles, workstations, and handrails are kept clear. Tables can be raised or purchased at an appropriate height for wheelchairs. Vincent's *Making the Library Accessible for All* has a clear and concise chapter on architectural and environmental accessibility.^[36]

Physical Books and Media

Physical books present inherent accessibility challenges to many people with visual disabilities, learning disabilities, and mobility disabilities. Libraries have a long history of collecting large-print books, which facilitate access by people with low vision. Another way to increase accessibility of physical books is to offer assistive technology that magnifies printed text, such as closed-circuit televisions. Many libraries arrange accommodations such as extended borrowing periods, proxy borrowers, renewal by phone, or extended reference help to facilitate access by disabled patrons. Communicating directly with patrons is the most effective way to learn what accommodations might help them use the library's books.

Under the 1996 Chafee Amendment, the NLS has permission to convert print materials to accessible formats, such as audio and Braille, without being subject to copyright law. Materials converted under the Chafee Amendment can only be distributed to eligible borrowers with a documented disability. These materials represent only a small fraction of the books published in any given year.

Standard type can often be made accessible through scanning. Scans can be run through optical character

recognition programs to produce text that can be converted to audio, Braille, more readable font, or large print. In 2013, the University of California, Berkeley, library announced that it will scan materials on demand for students with disabilities as part of an out-of-court settlement following structured negotiations with four students.^[37]

Deaf and hard-of-hearing patrons can access a much larger proportion of a library's holdings than visually disabled patrons, but videos may present an accessibility challenge. Many DVDs and Blu-Rays include captioning. Some libraries lend audio-described videos, which provide narration of the film's action for blind viewers.^[36]

Services and Programming

Libraries offer a wide range of programs, classes, book clubs, and other events. One way to avoid excluding people with disabilities from events is to publicize the fact that sign language interpretation or other accommodations are available if the library is notified a certain number of days in advance. Providing reasonable accommodations so that people with disabilities can participate in library programs is not only ethical, but likely falls under the ADA's provision that no individual should "be denied the benefits of the services, programs, or activities of a public entity."^[38]

Staff delivering presentations can increase accessibility by making sure slides and visual aids are clear and readable, with large text. White text on a dark background is easier to read by people with low vision.^[36]

Libraries increasingly produce video tutorials. An article by Oud offers guidance for creating accessible screencasts.^[39] She recommends Captivate or Camtasia for creating accessible videos. Best practices for accessibility include captioning, keyboard alternatives to mouse clicks, avoiding videos that start automatically, and including either alt text or spoken narration that describes what is happening onscreen. She writes that closed captioning (hidden by default) is preferred over open captioning (visible by default) because open captioning has been shown to be distracting to nondisabled users.

Many libraries provide programs specifically geared for people with disabilities. The Seattle Public Library, for example, hosts a book club conducted in American Sign Language. Several books and websites offer suggestions for programming for children and youth on the autism spectrum.^[40,41]

There is a long tradition of programs that deliver library materials directly to people's homes, historically called "homebound" or "housebound" services. These programs serve people who have difficulty getting to the library for a variety of reasons, including age, illness, and disability. In a 2004 study of home library service in the United Kingdom, Ryder found that libraries provide home library service to over 120,000 people and that

volunteers—often in combination with paid staff—support programs in over half of responding libraries. Only 62% of responding libraries publicize their home library service, partly due to fear of not being able to cope with demand, which may make them legally vulnerable under the UK's Disability Discrimination Act.^[42]

ELECTRONIC RESOURCE ACCESSIBILITY

Born-digital electronic resources have the potential to be more inherently accessible than print since assistive technology can modify text in a variety of ways to make it possible for people with disabilities to access. Assistive technology can change font size, style, or color; convert print to spoken word; or convert print to Braille. Other types of assistive technology allow users to use speech for text input or to navigate resources using a keyboard, mouth stick, or head wand. Unfortunately, many websites and electronic resources contain features that make them difficult or impossible to navigate using assistive technology.

Nina McHale provides a concise overview of web accessibility guidelines.^[43] Accessible web design is defined by two major sets of guidelines: the Web Content Accessibility Guidelines (WCAG), which are produced by the World Wide Web Consortium (W3C) and followed voluntarily, and the guidelines of Section 508 of the Rehabilitation Act, which are mandatory for federal agencies.

Many web accessibility guidelines are related to website performance on assistive technologies such as screen readers, while some, such as the recommendation to provide text transcripts of videos, address accessibility needs that are not related to screen readers.

Tatomir and Durrance developed a 10-point checklist, the Tatomir Accessibility Checklist, which provides a quick overview of some key components of accessibility. The checklist was inspired by a combination of the WCAG guidelines, Section 508 guidelines, and personal experience.^[44] The 10 elements of the Tatomir Accessibility Checklist are

1. Accessible versions of PDF web pages and documents
2. Skip navigation and jump-to links
3. Clearly labeled page elements
4. Text captions for tables, images, graphics, graphs, and charts
5. Limited use of incompatible programming languages and scripts
6. The absence of identically named page elements
7. Text transcripts of videos, animations, and podcasts
8. Logical and consistent page organization
9. Absence of timed responses
10. Digital forms and functionalities accessible and usable with adaptive technologies^[44]

Accessibility often goes hand in hand with usability. Accessible websites tend to be well-structured, quick to load on slow connections, compliant with web authoring standards, optimized for search engines (due to semantic markup), and easy to view on mobile devices.^[36]

Accessibility of electronic resources is relatively well covered in the library literature, although gaps still exist in many areas, such as usability testing by people with disabilities.^[33] Schmetzke edited special accessibility issues of *Library Hi Tech* in 2002^[45,46] and 2007.^[47] In 2012, Booth edited a special accessibility issue of *Library Technology Reports*.^[48]

Vendor Databases

One of the more troubling findings in the literature on electronic accessibility is that many vendor-supplied databases, to which large portions of library budgets are dedicated every year, do not meet accessibility standards. Tatomir and Durrance studied 32 vendor databases and found only 9 to be moderately accessible; most were either marginally accessible or inaccessible.^[44] Tatomir and Durrance gave relatively high marks to government websites, Google Scholar and Google Books, JSTOR, ProQuest, and OCLC World Cat. They noted that as of 2010 important accessibility elements were missing from databases produced by Gale, Lexis-Nexis, and Elsevier Science Direct. EBSCO databases were marginally accessible. Through a questionnaire directed at database vendors, Dermody and Majekodunmi found that most vendors did not work with people with disabilities to conduct usability tests.^[49]

The ASCLA maintains an online toolkit entitled *Think Accessible Before You Buy*, which provides checklists and questions to ask when evaluating electronic resources for accessibility.^[50] Libraries can require that potential vendors submit a Voluntary Product Accessibility Template (VPAT), a standardized document for reporting a product's compliance with accessibility standards. Many federally funded projects require a VPAT.^[51]

The Universal Accessibility Interest Group of the Association of College and Research Libraries maintains an online guide to resources on web accessibility, which as of this writing included information on vendor databases and LibGuides in addition to websites.^[52] Mulliken compiled a list of statements from vendors on their products' accessibility or lack thereof, which is no longer being maintained but remains informative.^[53]

Library Websites

Website accessibility may be a new field for many managers of "homegrown" library websites, and even for some professional web designers. Several websites and books outline small changes that can make a big difference for accessibility.^[36,54,55]

Comeaux and Schmetzke have collected longitudinal data on accessibility of North American academic library websites since 2002. In both 2010 and 2012, approximately 60% of websites were approved by Bobby 3.1.1, an automated checking tool.^[56] Maatta Smith used another checking tool, the WebAIM Accessibility Evaluator, for a 2014 study of 127 urban public libraries in the United States. She found that all websites contained some errors, with the most common being contrast errors (low contrast between text and background), missing alt text (no text alternative to images or video), and missing form labels (no navigational aids to help users identify and fill out forms).^[57]

Circulating Equipment

Increasingly, libraries circulate electronic equipment such as e-readers. Some e-readers are accessible to people with print disabilities, and some are not. The Free Library of Philadelphia and the Sacramento Public Library have both been sued for loaning inaccessible e-readers.^[58] The Department of Justice and Department of Education issued a Dear Colleague letter in 2010 stating any e-readers used by colleges and universities should offer text-to-speech functionality.^[59]

Assistive Technology

Many libraries provide assistive technology, also known as adaptive technology, for patrons' use. Vincent's book *Implementing Cost-Effective Assistive Computer Technology* provides an overview of options and considerations.^[60] Decisions about what technology to offer should be based on assessment of local needs.

STAFF TRAINING

One of the most important accessibility resources a library can offer is quality public service. All public services staff should know the library's accommodation procedures and the basics of using assistive technology within the library, including what is available through operating systems, browsers, and Microsoft Office. Accessibility information can be compiled in a staff manual easily accessible from service points. Training can be provided in-house, with outside trainers, through webinars, or through attendance at conferences.^[36]

In a qualitative study of library access, Clayton Copeland quotes from interviews with several people with disabilities. One of the participants, Nate, offers his impression of library staff attitudes:

...librarians are among the people who are most interested in helping people...their whole job is to help you find the book that you want and maybe even the book that

you didn't even know you wanted. And I think that tends to carry over into how they treat people with disabilities. Now in a modern situation where all jobs are getting more and more duties put on top of them, and cutting back on how many staff there are...If anybody comes along and needs a little extra work [deep sigh], that can be a problem. And certainly, you know, I think they catch their breath before they take on a whole new area. But I don't find a lot of resistance (Copeland,^[61] p. 235).

As Nate observes, the vast majority of library staff are friendly and willing to help, but many are unsure and hesitant when it comes to disability issues. Clear policies and staff training on effective communication with people with disabilities can increase the quality of service and decrease staff uncertainty and anxiety.

The tipsheets provided by the ASCLA present a good overview of best practices and etiquette. For example

Staff should ask, "What's the best way I can help you?" when a patron requests assistance. Let the person guide you.

After offering assistance, wait for acceptance; don't be afraid to ask questions if you aren't sure about something.

Respect the patron's privacy. Do not ask questions about his or her disability or its cause.

Understand that the adaptive equipment of a person with a disability is an extension of his or her body—this is true for adults and children. Ask for the person's permission before touching or moving the equipment.

Always speak directly to a person with a disability—not the person's companion, aide, or sign-language interpreter.^[62]

Use normal language. "See you later" will not offend visually impaired persons.^[63]

Written library policies can include statements that affirm the institution's commitment to the ADA and to providing access to all patrons. Policies and procedures can also outline the steps a library will take if it receives a complaint or request. Some libraries might write transition plans for changes that are not yet financially or logistically feasible.^[64]

Library Staff with Disabilities

People with disabilities are underrepresented in librarianship and library work. As the library profession works to increase diversity in its ranks, disability is one of the areas targeted. The ALA Century Scholarship is provided annually to support a library school student with disabilities. Few empirical studies of librarians with disabilities have been conducted. A study of academic library managers in the Republic of Ireland found that they were aware of the

need to accommodate disabilities, but that one-third of their libraries did not have procedures in place to address requests for reasonable accommodation.^[65]

In the title of a 1995 opinion piece in *American Libraries*, Barlow exhorted, “Don’t Just Serve People with Disabilities—Hire Them.” She recounts the struggles and successes of several library employees with disabilities, gathered from a listserv query. Marilyn McLean, then head of science reference at Boston Public library, who has spina bifida, stated, “I frequently have had students writing paper or other people call about disabilities or birth defects, and I can often lend a personal touch to the reference encounter” (Barlow,^[66] p. 722).

Fran Ziglar, a wheelchair user, wrote about her 31-year career at the Nashville Public Library in a 2006 *Tennessee Libraries* article. She writes, “There have been a few issues about accessibility: what to do when the elevator broke; early accessible bathroom stalls with curtains rather than doors, etc. Overall, I think that a sense of humor, concerned supervisors, and supportive co-workers have made the way successful and meaningful.”^[67]

OUTREACH

Community members with disabilities might not know that the library has resources for them. Especially if they have had negative experiences with libraries in the past, the prospect of going to a library without knowing whether they will be able to carry out simple tasks could be daunting. Outreach is an important part of an accessibility strategy. Used here, outreach refers to communication with community members who may not be library users and includes both informing people about what the library offers and asking them about what they need. Outreach might be conducted through partnerships with disability organizations, schools, or senior centers. Outreach could include co-hosted events or inclusion of library information in outside organizations’ marketing materials.

In *Making the Library Accessible for All*, Vincent recommends that every library recruit a group of “accessibility resource people.” This advisory group would provide ongoing feedback on local needs and accessibility issues. Accessibility resource people could provide information either through in-person meetings or electronic communication; she recommends SurveyMonkey as the most accessible of the free online survey tools. Vincent’s book includes a sample list of questions for initial information-gathering. She quotes Alan Bern of the Berkeley Public Library: “There is, perhaps, nothing more important than a focus group—or, better, an ongoing Advisory Group—to discuss accessibility issues at your library. You WILL get requests you cannot meet—and even off-base questions and requests—but the number of spot-on questions and requests AND unexpected, fantastic ideas far outweighs any negative outcomes” (Vincent,^[36] p. 3).

Once people with disabilities feel welcome in the library, they are often enthusiastic and active patrons. Vincent quotes computer accessibility expert Marc Sutton: “There are many books and magazines available through online library databases that would otherwise not be accessible to print-impaired persons. Often, a patron just needs a little help finding these items and then a whole new world of knowledge opens up” (Vincent,^[36] p. xii).

DISABILITY AS SUBJECT MATTER

Discussions of disability and libraries often focus solely on the accessibility of resources and services. Another important aspect of disability, however, is disability as subject matter. Materials related to disability culture, art, and politics, as well as materials created by people with disabilities, are of interest to library users with and without disabilities. Strong collections will include materials that reflect the intersections of disability with other aspects of diversity, including class, race, gender, and sexual orientation.

Collection development in the disability field may involve turning to some specialized reference sources or small publishers. Many mainstream depictions of disability, especially in film, continue to rely on stereotypes, portraying people with disabilities either as villains or as one-dimensionally inspirational or tragic figures.^[68] The Schneider Family Book Awards, administered by the ALA, are given yearly to children’s and young adult books about the disability experience. A bibliographic essay by Cole, focusing on disability studies, also contains useful references to materials on disability history, culture, and memoir.^[69] An annotated bibliography by Klauber, although out of date, lists categories of books providing practical information about aspects of living with a disability: College and Careers; Easier Living; House and Garden; Recreation and Travel; and Love, Marriage, Baby Carriage.^[70]

Cataloging and Indexing

Because the terminology used to describe disability has historically reflected discriminatory cultural attitudes, library catalogs can contain archaic or insensitive words. The word “handicapped,” for example, is commonly found in indexes despite not being in general use. Emmett and Catherine Davis discussed subject access to disability materials in the 1980s *Mainstreaming Library Service for Disabled People*, where they critiqued then-current Library of Congress headings such as *Idiocy* and *Castration of Criminals and Defectives*.^[71] In a 2013 study of award-winning books about disability for youth, Kaney found that catalog terms failed to adequately represent many important disability issues.^[72] In a 2014 article, Koford interviewed nine disability studies scholars about

their impressions of subject headings, finding that they often encounter and use nonpreferred language when searching.^[73]

Catalogers and indexers continuously change standards to reflect changes in society and language. Drabinski argues that problematic subject access terms can be used as pedagogical tools, helping library users better understand historical and social aspects of information.^[74] In the *Disability Studies Reader*, disability studies scholar Lennard Davis recounts a meeting between the Committee on Academics with Disabilities and a bibliographer from the MLA Bibliography. He writes, “an article on ‘crippled saints’ could not be searched by computer because the word ‘crippled’ was disallowed by MLA regulations as constituting discriminatory language. The bibliographer therefore filed the article under ‘saints’ thus rendering it unretrievable by anyone with an interest in disability” (Davis,^[7] p. xvii). This story illustrates the idea that access structures cannot be fixed by replacing terminology; rather, structures serve as evidence of history, struggle, and change. In practical terms, the variety of words historically used to describe disability means that searching for disability information is challenging and might require extra time and creativity.

CONCLUSIONS

Access to information, both about disability and about other topics, is essential for people with disabilities. Many disabled people have had positive experiences finding information through websites, databases, museums, archives, and libraries; at the same time, many have encountered barriers that prevented them from accessing the full range of information available to nondisabled people. Awareness of some disability issues, such as the importance of large-print books, is high within the library profession, while awareness of other issues, such as the poor accessibility record of many vendor-supplied databases, is low. There are many gaps in the library and information science literature on disability, and more studies that include disabled people as participants are needed. Some key principles that emerge in the literature are

- People with disabilities should be involved in the accessibility evaluation and planning process.
- Universal design, when it is possible, is more efficient and equitable than retrofitting nonaccessible structures or building alternate versions. This principle applies both to physical spaces and to electronic resources.
- Designing for accessibility often leads to usability. For example, large and clear signs benefit not only people with low vision or cognitive disabilities, but also nondisabled library users. Websites designed for accessibility tend to perform well not only on screen readers, but also on slow connections and mobile devices.

Providing equitable access to information for all people, including those with disabilities, is an ongoing process. Asking questions and opening lines of communication is essential to improving library services to people with disabilities.

Abstract

Personal information management (PIM) refers to the practice and the study of the activities a person performs in order to acquire or create, store, organize, maintain, retrieve, use, and distribute information in each of its many forms (paper and digital, in e-mails, files, web pages, text messages, tweets, posts, etc.) as needed to meet life's many goals (everyday and long term, work related and not) and to fulfill life's many roles and responsibilities (as parent, spouse, friend, employee, member of community, etc.). PIM activities are an effort to establish, use, and maintain a mapping between information and need. Activities of finding (and refinding) move from a current need toward information, while activities of keeping move from encountered information toward anticipated need. Meta-level activities such as maintaining, organizing, and managing the flow of information focus on the mapping itself. Tools and techniques of PIM can promote information integration with benefits for each kind of PIM activity and across the life cycle of personal information. Understanding how best to accomplish this integration without inadvertently creating problems along the way is a key challenge of PIM.

INTRODUCTION

Personal information management (PIM) refers to the practice and the study of the activities a person performs in order to acquire or create, store, organize, maintain, retrieve, use, and distribute information in each of its many forms (paper and digital, in e-mails, files, web pages, text messages, tweets, posts, etc.) as needed to meet life's many goals (everyday and long term, work related and not) and to fulfill life's many roles and responsibilities (as parent, spouse, friend, employee, member of community, etc.) or, to paraphrase, PIM is the art of getting things done in our individual lives through information.^[1] PIM places special emphasis on the organization and maintenance of personal information collections (PICs) in which information items, such as paper documents, electronic documents, e-mail messages, digital photographs, web page references, and handwritten notes, are stored for later use and repeated reuse.^[2]

PIM provides a productive meeting ground for several disciplines including cognitive psychology and cognitive

science; human-computer interaction, information science, and human-information behavior; and the fields of data, information, and knowledge management. In a world increasingly defined by the information we receive, send, and share, the ability to manage this information is one of life's essential skills.

One ideal of PIM is to always have the right information in the right place, in the right form, and of sufficient completeness and quality to meet the current need. This ideal is far from reality for most people. In practice, people do not always find the right information in time to meet their needs. It may be that the necessary information is not found or may arrive too late to be useful. Or information may arrive too soon and then be misplaced or forgotten entirely before opportunities for its application arrive. People forget to use information even when (or sometimes because) they have taken pains to keep it stored somewhere for future use.

To better “keep found things found,”^[3] people may store their information in multiple locations and in multiple applications, using organizational schemes that are roughly comparable but still inconsistent (often in

important ways). The result is *information fragmentation*^[4]—the information people need is scattered widely, making activities of PIM more difficult:

- *Maintaining and organizing* personal information is more difficult when so many separate stores of information must be considered. Are organizations the same or at least consistent? Which version of a document is current? Is information getting backed up?
- *Managing for privacy, security, and the overall flow of information* (incoming and outgoing) is more difficult when a person's information is so widely scattered. What have people shared and with whom?^[5] Is there an "Achilles heel" in a person's data protection efforts?
- Information fragmentation makes more difficult even the basic, every-minute activities of *keeping* and *finding*. Where/how to keep an important file, reference, or reminder when there are so many alternatives to choose from? And where among these alternatives should people later look for this information?

Information fragmentation is manifest in the many sources of information a person must consult to make even simple decisions. The decision to accept a dinner invitation, for example, may depend upon the information to be found in digital calendars, paper calendars (e.g., a shared household calendar), web pages, and e-mail exchanges. PIM activities in general take longer and are more prone to error when information is scattered.

While new applications, tools, and devices often increase information fragmentation, this does not have to be the case. Some tools and techniques of PIM promote information integration, which can simplify PIM activities and have benefits across the life cycle of personal information. Tools can also simplify the sharing and exchange of information across devices and people, and can help users to see unified views of their information spaces.

In the following sections, we provide

- A brief history of PIM
- An analysis of PIM including the several senses in which information can be "personal" and major kinds of PIM activity
- A selective review of PIM research especially as this relates to major kinds of PIM activity
- Concluding notes on some of the significant challenges and opportunities for the PIM field of study in the years ahead

A BRIEF HISTORY OF PIM

PIM is a new field with ancient roots. When the oral rather than the written word dominated, human memory was the primary means for information preservation.^[6] As information was increasingly rendered in paper form, tools

were developed over time to meet the growing challenges of management. For example, the vertical filing cabinet, now a standard feature of home and workplace offices, was first commercially available in 1893.^[7]

The modern dialog on PIM is often traced to the publication of "As We May Think" by Vannevar Bush at the close of World War II.^[8] Bush expressed a hope that technology might be used to extend our collective ability to handle information and to break down barriers impeding the productive exchange of information.

The 1940s also saw the development of Shannon's theory of communication that laid the groundwork for a quantitative assessment of information.^[9] Key to this theory is the notion that the information content of a message can be measured for its capacity to reduce uncertainty.

To understand information exclusively as the reduction of uncertainty can be seen as overly restrictive.^[10] As Buckland notes, "sometimes information increases uncertainty,"^[11] p. 351. Nevertheless, even as we search for complementary, qualitative characterizations of information (e.g., Dinneen and Brauner^[12]), a larger point in Shannon's work endures: The value of information is not absolute, but relative to a context that includes the intentions of the sender, method of delivery, and the current state of a recipient's knowledge. This holds true even when the sender and the recipient are the same person albeit separated in time, for example, when people place "appointments" in their calendars a week from today as a reminder to do something (e.g., "book plane tickets").

With the increasing availability of computers in the 1950s came an interest in the computer as a source of metaphors and a test bed for efforts to understand the human ability to process information and to solve problems. Newell and Simon pioneered the computer's use as a tool to model human thought.^[13,14] They produced "The Logic Theorist," generally thought to be the first running artificial intelligence program. The computer of the 1950s was also an inspiration for the development of an *information processing approach* to human behavior and performance.^[15]

After research in the 1950s showed that the computer, as a symbol processor, could "think" (to varying degrees of fidelity) like people do, the 1960s saw an increasing interest in the use of the computer to help people to think better and to process information more effectively. Working with Andries van Dam and others, Ted Nelson, who coined the word "hypertext,"^[16] developed one of the first hypertext systems, the Hypertext Editing System, in 1968.^[17] That same year, Douglas Engelbart also completed work on a hypertext system called NLS (on-Line System).^[18] Engelbart advanced the notion that the computer could be used to augment the human intellect.^[19,20] As heralded by the publication of Ulric Neisser's book *Cognitive Psychology*,^[21] the 1960s also saw the emergence of cognitive psychology as a discipline that focused primarily on a better understanding of the human ability to think, learn, and remember.

The computer as an aide to the individual, rather than a remote number cruncher in a refrigerated room, gained further validity from work in the late 1970s and through the 1980s to produce personal computers of increasing power and portability (for more on the history of the personal computer, see Refs.^[22–24]). These trends continue. Computational power roughly equivalent to that of a desktop computer of a decade ago can now be found in devices that fit into the palm of a hand (see Jones,^[25] Chapter 4, for discussion on the present and future of information “always at hand” via devices).

The phrase “personal information management” was itself apparently first used in the 1980s^[26] in the midst of general excitement over the potential of the personal computer to greatly enhance the human ability to process and manage information. The 1980s also saw the advent of so-called “PIM tools” that provided limited support for the management of such things as appointments and scheduling, to-do lists, phone numbers, and addresses. And a community dedicated to the study and improvement of human–computer interaction also emerged in the 1980s.^[27,28]

As befits the “information” focus of PIM, PIM-relevant research of the 1980s and 1990s extended beyond the study of a particular device or application toward larger ecosystems of information management to include the organization of the physical office^[29] and the management of paperwork.^[30] Malone^[31] characterized personal organization strategies as “neat” or “messy” and described “filing” and “piling” approaches to the organization of information. Other studies showed that people vary their methods for keeping information according to anticipated uses of that information in the future.^[32] Studies explored the practical implications that human memory research might carry in the design of, for example, personal filing systems^[33–35] or information retrieval systems.^[36] Studies demonstrated a preference for navigation (browsing, “location-based finding”) in the return to personal files,^[37] a preference that endures today notwithstanding significant improvements in search support^[38–41] and an increasing use of search as the preferred method of return to e-mails.^[42]

PIM, as a contemporary field of inquiry with a self-identified community of researchers, traces its origins to a special interest group session on PIM at the CHI 2004 conference^[43] and to a special National Science Foundation–sponsored workshop held in Seattle in 2005.^[44] (Since 2005, PIM workshops have been held roughly every 18–24 months, see: <http://pimworkshop.org/>.)

AN ANALYSIS OF PIM

A deeper understanding of what PIM *is* begins with definitions of associated concepts and the description of a

conceptual framework in which to interrelate key kinds of PIM activity.

The Information Item and Its Form

Information sent and received takes many *information forms* in accordance with a growing list of communication modes, supporting tools, and people’s customs, habits, and expectations. People still send paper-based letters, birthday cards, and thank you notes. But ever more so, people communicate using digital forms of information including e-mails, documents shared (as attachments or via a service such as Dropbox), and “tweets,” text messages, blog posts, Facebook updates, and personal web pages.

Across forms, it is useful to speak of an *information item* as a packaging of information. An item encapsulates information in a persistent form that can be managed. An information item can be created, stored, moved, given a name and other properties, copied, distributed, and deleted.

The concepts of information item and information form are helpful abstractions for considering aspects of PIM. For example, an e-mail message, as an item, packages together information such as a sender, receiver, subject, body text, and date sent. All e-mails, as befits their form, share common characteristics such as the expectation of a timely delivery (i.e., in seconds not days) and a timely response (i.e., within a day or two, not a month later). An e-mail message can be *transformed*, i.e., it can be copied to create a new information item of a different form. For example, a user may print the e-mail and view it in a paper form. Each form is associated with a distinct set of tools, techniques, habits, and expectations for interacting with and managing the information.

Personal Information

There are several senses in which information can be personal. Each represents a different relationship between the information and the person: Information can be owned by, about, directed toward, sent by, experienced by, or relevant to “me.” (See Table 1.) This definition and the several relationships captured in Table 1 form an inclusive definition of personal information. Prior work in PIM has at times limited the definition of PIM by not including some of these relationships.

Clearly, the senses in which information can be personal are not mutually exclusive. In many cases, the same information may be personal in several senses. For example, a folder of photos taken last Thanksgiving is information about the friends and family at the dinner—and about “me” (P2). The photos are owned by “me” (P1), and these represent events experienced by “me” (P5). The owner can also elect to share the photos with others via a service like Dropbox (P4).

Table 1 Information can be personal in any of several relationships to a person

	Relation to “me”	Examples	Issues
P1	Controlled by/owned by me	E-mail messages in our e-mail accounts; paper documents in a home office; computer files on a hard drive or in a web cloud service.	Security against break-ins, virus protection, backups to prevent data loss, etc. What to share and with whom? These questions apply both for paper filing cabinets and for folders in a service like Dropbox.
P2	About me	Credit history, medical records, web search history, records of library books checked out.	Who sees what, when, and under what circumstances? How is information corrected or updated? Does it ever go away?
P3	Directed toward me	E-mails, phone calls, drop-ins, TV ads, web ads, pop-ups. Also, invitations to join a share of a cloud service. Facebook posts. Tweets “@” you.	How to stay focused long enough to complete a task? “When I’m not interrupted by others, I interrupt myself! I worked nonstop today, but what did I accomplish?”
P4	Sent/posted/ shared by me	Sent e-mail, personal websites, published reports and articles, folders shared via a cloud service like Dropbox.	Who sees what when? Did the message get through? Am I making the “right” impression? Am I sharing the right information for our teamwork?
P5	For things experienced by me	Web history, photos (taken by others as well as by me), handwritten notes, full-motion videos from head-mounted cameras. ^[45]	How to get back to information again later? How to pick up where I left off (i.e., with a task, a book or episodes of a drama on Netflix)? How much history do I really need?
P6	Potentially relevant/ useful to me	Somewhere “out there” is the perfect vacation, house, job, lifelong mate. If only I could find the right information!	If only I knew (had some idea of) what I don’t know. But also... how to filter out information we don’t wish to see? (How to do likewise for our children?)

A Personal Space of Information

Each person has a single unique personal space of information (PSI) defined by the union of personal information

in each of its six senses as depicted in Table 1. A PSI affects the way its owner views and interacts with the rest of the world. A PSI also affects the way its owner is seen, categorized, and treated by others.

At its center, a person’s PSI includes all the information items that are, at least nominally, under that person’s control. At its periphery, the PSI includes information that the person might like to know about and control, but that is under the control of others. Included is information about the person that others keep. Also included is information in public spaces, such as a local library or the web, which might be relevant to the person.

Personal Information Collections

Personal information collections, referred to as PICs or simply collections, are personally managed subsets of a PSI. PICs are “islands” in a PSI where people have made some conscious effort to control both the information that goes in and how this information is organized. PICs can vary greatly with respect to the number, form, and content coherence of their items. Examples of a PIC include

- The papers in an office and their organization, including the layout of piles on a desktop and the folders inside filing cabinets
- A collection of projects each represented by a folder stored in a cloud storage service and accessed from different devices
- A collection of information items related to a specific project that are initially “dumped” into a folder on a person’s notebook computer and then organized over time as the project takes shape
- A reference collection of articles in digital format, organized for repeated use across projects
- Digital songs managed through a laptop computer or smartphone
- A collection of media (TV shows, movies, music) stored in a streaming service under a personal account, organized by some preference and including information such as ratings, watched/unwatched, and other notes

A PIC includes not only a set of information items but also their organizing representations, including spatial layout, containing folders, properties, and tags.

Activities of PIM

PIM activities are an effort to establish, use, and maintain a mapping between information and need, whether actual, perceived, or anticipated. Fig. 1 depicts a mapping between information and need as well as the activities of PIM that work with this mapping.

Information can arrive as aural comments from a friend, a billboard seen on the way to work, letters in

Fig. 1 PIM activities viewed as an effort to establish, use, and maintain a mapping between needs and information. Keeping and finding activities are interrupt driven (as prompted by incoming information or a need). M-level (meta-level) activities are broader in focus and more strategic in nature.

surface mail, or any number of digital items including e-documents, e-mail messages, Web pages, text messages, and tweets.

Needs can arise from internal or external sources. A person may recall, for example, that she needs to make plane reservations for an upcoming trip. The need may arise from the question posed by a colleague in the hallway or a manager's request during a meeting. External needs can also be evoked by an information item, such as an e-mail message or a web-based form.

Connecting between need and information is a mapping. Only small portions of the mapping have an observable external representation. Much of the mapping has only a hypothesized existence in the memories of an individual. Large portions of the mapping are potential and not realized in any form, external or internal. A sort function or a search facility, for example, has the potential to guide from a need to the desired information.

However, parts of the mapping can be observed and manipulated. The folders of a filing system (whether for paper or digital information), the layout of a desktop (physical or virtual), and the choice of names, keywords, and other properties for information items all form parts of an observable fabric helping to knit need to information.

Activities of PIM can be grouped and interrelated with reference to Fig. 1 as follows:

- **Keeping activities** map from encountered information to need (immediate or anticipated). This grouping includes decisions concerning whether to attend to information in the first place and, then, whether to make any effort to keep the information. Some information—the time on a clock or a sports score, for example—is “consumed” immediately with no need to keep the information for later access. Much of the information people encounter is simply ignored. For

the subset of encountered information to be kept for later use, questions arise regarding how the information should be kept. Should information items be piled (where?), filed (which folder?), tagged (with which tags?), or committed to memory?

- **Finding/refinding activities** map from need to information. This grouping includes explicit search queries as posted to a web-based search service or to a computer desktop-based search facility. The grouping also includes various activities of sorting, navigation, and “nosing around” that people use to get back to information for reuse.
- **Meta-level activities** focus on the mapping itself as a way of connecting together information and need. Meta-level activities include efforts to maintain (through backups, periodic cleanups, updates, and corrections) and organize (via schemes of piling, filing, or tagging) information; manage privacy, security, and the flow of information (e.g., through subscriptions, friendships, policies of disclosure, firewalls, virus protection); measure and evaluate (how are supporting tools and strategies working?); and make sense of and use of personal information (“What is the information telling me? What should I do?”).

PIM RESEARCH

PIM research can be organized according to PIM activity as follows:

Finding/Refinding: From Need to Information

The focus of a finding/refinding activity can be on information in a public space such as a physical library or the web, or focus can be on the information a person owns in a private space such as an office filing cabinet, the hard drive of a personal computer, or a cloud storage service.

A large body of information seeking and information retrieval research applies especially to finding public information.^[46–50] There is a strong personal component even in efforts to find new information, never before experienced, from a public store such as the web. For example, efforts to find information may be directed by a personally created outline or a to-do list. In addition, information inside a person's PSI can be used to support a more targeted, personalized search of the web.^[51]

The search for information is often a sequence of interactions rather than a single transaction. Bates^[52] describes a “berry picking” model of searching in which needed information is gathered in bits and pieces through a series of interactions, and during this time, the user's expression of need, as reflected in the current query, evolves. Teevan et al.^[53] note that users often favor a stepwise approach even in cases where the user might have sufficient

knowledge to access the information more quickly and more directly via a well-formed query. The stepwise approach may preserve a greater sense of control and context over the search process and may also reduce the cognitive burden associated with query formulation. For frequent information needs, users may well-trod paths of access, whereas for less common needs, search may be more likely to play a role.^[54]

People may find (rather than refind) information even when this information is ostensibly under their control. For example, items may be “pushed” into the PSI (e.g., via the inbox, automated downloads, web cookies, the installation of new software, etc.), and a person may have no memory or awareness of these items. If these items are ever retrieved, it is through an act of finding, not refinding. Memories of a previous encounter with an information item may also fade so that its retrieval is more properly regarded as an act of finding rather than refinding.^[55] While searching for information, one might come across information that, though not relevant to the current search, is relevant to another project. Or one may find information that is incorrectly filed or is in a “download” folder awaiting more proper organization (e.g., as part of “spring cleaning”).

Lansdale^[26] characterized the retrieval of information as a two-step process involving interplay between recall and recognition. The steps of recall and recognition can iterate to progressively narrow the search for the desired information—for example, when people move through a folder hierarchy to a desired file or e-mail message or navigate through a website to a desired page.

But a successful outcome in a refinding effort depends upon the completion of another step preceding recall: A person must remember to look. A person may know exactly where an item is and still forget to look for the item. It is also useful to consider a final “repeat?” step. Failure to collect a complete set of information (e.g., all potential conflicting commitments before accepting a proposed meeting time) can mean failure for the entire finding episode.

Refinding, then, is a four-step process with a possibility to fail at each step:

Step 1. Remember (to look). Many opportunities to refind and reuse information are missed for the simple reason that people forget to look. This failure occurs across information forms. In a study by Whittaker and Sidner,^[56] for example, participants reported that they forgot to look in “to do” folders containing actionable e-mail messages. Because of mistrust in their ability to remember to look, people then elected to leave actionable e-mail messages in an already overloaded inbox.

Web information is also forgotten. In one study of web use, participants complained that they encountered web bookmarks; in the course of a “spring cleaning,” for example, that would have been very useful for a project whose time had now passed.^[57] In a study where participants were cued to return to a web page for which they had a web bookmark, the bookmark was used on less than 50%

of the trials.^[58] Marshall and Bly^[59] report a similar failure to look for paper information (newspaper clippings).

Remembering to look depends, in part, upon the effective use of *attentional spaces*^[3], such as the surface of a physical desktop, a computer desktop, or the visible region of an inbox’s display.

Steps 2 and 3. Recall and recognize. Recall and recognition can be considered together as two sides of a dialog between people and their PSIs. A person types a search word (recall) and then scans through a list of results (recognition). A person’s recall is often partial. For example, a person may have some sense that the e-mail message was sent by a person whose name starts with an “S” (“Sally?”). As prompted by this partial recall, she might then sort e-mail messages by sender and then scan through the “s” section of this sorted list.

Though any act of retrieval involves a combination of recall and recognition, their relative importance can vary with method. Recall is typically more important in a search, i.e., a person initially recalls the keywords to be used in a search query (though, of course, the person might have recognized these words from a web page previously viewed and simply copied them into the query). Recognition is typically more important in what is alternately referred to as location-based finding, orienteering, browsing, or, simply, *navigation*.^[37,53,60]

Many PIM studies have determined that users prefer to return to information, most notably the information kept in personal digital files, by navigating rather than searching.^[37–39,41,53,60–62] This may be surprising; the use of navigation often depends on remembering or recognizing a specific path to the folder in which the item was stored, while a search is more flexible insofar as users can specify in their query any attribute they happen to remember about the information item. Fertig et al. argued back in 1996^[63] that an observed preference for navigation over search was due to the limitations in the search technologies at the time and that improvement in search would inevitably lead to a shift from navigation to search as the preferred method of return. Commercial PIM search engines have indeed improved dramatically. However, the combined results of a large-scale study and a longitudinal study^[39] indicated that the availability of new and improved search facilities (such as Mac Spotlight) did not result in more search than was observed for older and slower search facilities (such as Sherlock). Search was apparently used only as last resort on those occasions when participants could not remember the location of the files they sought. This finding gains further support from a recent log study indicating that participants used search in only 4.2% of their retrievals.^[64]

One explanation for a preference for navigation over search in the return to personal information derives from a persistent, general finding in cognitive psychology literature that people are better able to recognize than to recall information previously encountered (see Neisser^[21]). As noted previously, in the interplay between recognition and

recall, recognition is more dominant in navigation and recall is more dominant in search.

“Navigation” to digital files and other information is, of course, done in a computing environment that is much less rich in sensory experience than the physical environments people navigate through on a daily basis. But perhaps digital and physical navigation engage, at some level, some of the same processes. In support of this intuition is a recent, innovative fMRI study^[65] demonstrating that, when people use navigation as a means to retrieve their own personal files, they are using some of the same brain structures as when navigating in the physical world (i.e., the posterior limbic regions). In contrast, search activates Broca’s area, commonly observed in linguistic processing.

Another recent study asked people either to navigate to or search for a target file. As people did so, a list of words was read to them in the background. People were later better able to remember these words, presumably a linguistic task, when navigating rather than searching.^[66]

The argument for the observed preference for navigation to search in the retrieval of personal information would then appear to be very strong indeed. Navigation places higher reliance on recognition, which people are usually better at than recall. Navigation to digital information engages some of the same neural structures as are engaged in physical navigation, which is a highly practiced skill in people. Furthermore, navigation places fewer demands than search on linguistic processing and the regions of the brain involved in linguistic processing, thus freeing this capacity for use elsewhere in a person’s computing interactions.

But the discussion continues. Just as navigation vs. search and the use of supporting tools appear to engage different facilities and different areas of the human brain, there is reason to suppose that other activities, too, as done through the computer and computer-based tools, will vary qualitatively in the nature of processing demands placed upon the user. Studies done in the 1980s, for example, suggested a significant shift in processing demands with the advent of support for full-screen, WYSIWYG text editing.^[67–69]

A more recent study suggests that the now-standard support for fast, indexed “desktop” search may be having some impact, not on the preferred method for return to personal digital files, which remains navigation, but on another form of personal information: e-mail.^[42] Consistent with this is the finding that people are less inclined to invest in the organization of e-mails into folders electing instead, for example, to leave information in a single larger folder or even the inbox.^[70]

How, then, to account for this apparent disparity—that even as preference may be shifting toward search as a primary method for return to e-mails (i.e., those that aren’t readily available in the current inbox display)—people persist in navigating to digital files? And why is this despite the fact that essentially the same fast, indexed search support can be applied to both e-mails and files?

We consider one last explanation that relates to the well-established *primacy* effect of psychology

research:^[21] Under a *first-impressions* hypothesis,^[42] people’s first choice of return aligns with their initial experience with the encountered information. Given adequate search support, people might naturally prefer to retrieve an e-mail via a search on the sender or subject since this information is often an initial focus of attention (and is used as a basis for deciding whether to attend to the e-mail). Likewise, since people must initially place a file into a folder (unless they accept a “My Documents” default), navigation to the folder is a first choice of return to the file. Given better, more universal support for tagging, for example, people might be more likely to prefer search (on tags) as a preferred method of return to documents and other files. (But see the section on keeping for its discussion of folders vs. tags). Conversely, were people first to create and exchange e-mails “in place,” in the context of a project (folder) they are working on, they might prefer navigation as a method of return (see, e.g., work on the Project Planner/Planz representing one attempt to situate e-mail by project.^[71,72])

Habits change slowly and desktop search support continues to improve. Desktop search is increasingly integrative and ever closer to an ideal where anything that can be remembered about an information item or the circumstances surrounding encounters with it (e.g., time of last use or nearby events) can be used to help find this item.^[35,73,74]

Search vs. navigation? Since many circumstances of real-world information retrieval are likely to involve a little of both,^[53] a challenge in our tool-building efforts toward better PIM is to support artful ways of combining and seamlessly switching between these two general methods of information retrieval. Toward this goal is recent work that explores ways to integrate search and navigation by highlighting certain navigational pathways based upon the results of a background search.^[75]

Step 4. Repeat? In many instances, information need is not for a single information item but, rather, for a set of items whose members may be scattered in different forms within different organizations. If the likelihood of successful retrieval of each item is strictly independent from the others, then the chances of successful retrieval of all relevant items go down as their number increases. So even if the likelihood of success for each of four items is high, the retrieval of all four items is presumably much lower.

However, in situations of *output interference*, items retrieved first interfere with the retrieval of later items so that chances of successful retrieval of the whole set are worse than predicted by a strict independence of individual retrievals.^[76] The effect can be explained with reference to interference paradigms of human memory retrieval such as the basic *spreading activation model*.^[77] As a useful simplification, think of items in a simple set as primarily indexed and accessed through a single node such as “People in my book club.” In this case, during a retrieval attempt, each item in the set competes with other items for a limited amount of activation. Moreover, the successful retrieval of

initial items strengthens their connections to the access node at the expense of later items not yet retrieved, e.g., as “Susan” is retrieved, the corresponding link to “People in my book club” is strengthened at the expense of, say, the link to “Jonathan” (not yet retrieved).

The chances of successfully retrieving all members of a set can also be much better than predicted by independence. Certainly, retrieval is better if all items are in the same larger unit—a folder or a pile, for example. Retrieval may also be better if items of a set have an internal organization or are interconnected to one another so that the retrieval of one item actually facilitates the retrieval of other items.^[78] By one explanation, activation sent to one item can be “shared” with other items through these interconnections.^[79]

Keeping: From Information to Need

Many events of daily life are roughly the converse of finding events: People encounter information and try to determine what, if anything, they should do with this information, i.e., people must match the information to current or anticipated needs. Decisions and actions relating to encountered information are collectively referred to as *keeping* activities.

The ability to effectively handle information that is encountered by happenstance may be essential to a person’s ability to discover new material and make new connections.^[80] People also keep information that they have actively sought but do not have time to process currently. A search on the web, for example, often produces much more information than can be consumed in the current session. Both the decision to keep this information for later use and the steps to do so are keeping activities.^[57]

Keeping activities are also triggered when people are interrupted in the midst of a current task and look for ways of preserving the current state so that work can be quickly resumed later.^[81] For example, people keep appointments by entering reminders into a calendar and keep good ideas or “things to pick up at the grocery store” by writing down a few cryptic lines on a loose piece of paper.

People *keep* not only to ensure they have some particular information later, but also to build in a reminder to look for and use that information. Failure to remember to use information later is one kind of prospective memory failure.^[82–84] People may, for example, self-e-mail a web page reference in addition to or instead of making a bookmark because the e-mail message with the reference appears in the inbox where it is more likely to be noticed and used.^[57]

Research relating to keeping points to several conclusions: 1) keeping is difficult and error-prone; 2) keeping “right” has gotten harder as the diversity of information forms and supporting tools has increased; and 3) some costs of keeping “wrong” in the digital realm have gone away due to advanced search capabilities, but challenges remain.

Keeping is difficult and error-prone. The keeping decision is multifaceted. Is the information useful? If so,

do special steps need to be taken to keep it for later use? How should the information be kept? Where? On what device? In what form should the information be kept? The keeping decision can be characterized as a signal detection task subject to errors of two kinds: 1) an incorrect rejection (“miss”) when information is ignored that, as time tells, should have been kept (e.g., those paper receipts that are needed now that the tax return is being audited) and 2) a false positive when information kept as useful (“signal”) turns out not never to be used later. The physical and digital clutter in our lives is often evidence for false positive decisions.

Filing information items—whether paper documents, e-documents, or e-mail messages—correctly is a cognitively difficult and error-prone activity.^[26,31,56] Difficulty arises in part because the definition or purpose of a folder or tag is often unclear from its label (e.g., “stuff”) and then may change in significant ways over time.^[56,85] Filing and tagging difficulties increase if people do not recall the folders or tags they have created previously and then create new folders or tags rather than reusing those already created.^[56]

But placing (or leaving) information items in piles, as an alternative to filing, has its own problems. In Malone’s study,^[31] participants indicated that they had increasing difficulty keeping track of the contents of different piles as the number of piles increased. Experiments by Jones and Dumais^[86] suggest that the ability to track information by location alone is quite limited. Moreover, the extent to which piles are supported for different forms of information is variable, limited, and poorly understood.^[87]

Kwasnik^[32] identified a large number of dimensions that might potentially influence the placement and organization of paper-based mail and documents in an office. Overall, a document’s classification was heavily influenced by the document’s intended (anticipated) use—a finding subsequently reproduced by Barreau.^[88] Similarly, Jones et al.^[57] observed that the choice of method for keeping web information for later use was influenced by a range of considerations or functions. Marshall and Bly^[59] also note that the reasons for keeping information vary and are not necessarily task related or even consciously purposeful.

Keeping “right” is harder when information is more fragmented. An act of keeping might be likened to throwing a ball into the air toward a point where we expect to be at some future point in time and space. The ongoing proliferation of information forms and supporting tools and gadgets makes keeping activities even harder. The information people need may be at home when they are at work or vice versa. It may be on the wrong device. Information may be “here” but locked away in an application or in the wrong format so that the hassles associated with its extraction outweigh the benefits of its use. Users employ a variety of methods to ensure that information is in the “right” place when it is needed and methods may require additional, manual work to transfer and synchronize

information across devices and locations. Personally imposed and employer-imposed information boundaries may further fragment the information owned by or under the control of the user (P1—see Table 1) with significant impact on activities to maintain and organize and also to manage the flow of information.^[89] Considerations for these and other *meta-level activities* are further described later in this section.

People must contend with the organization of e-documents, e-mail messages, web pages (or references to these), and possibly also a number of additional forms of digital information including phone messages, digitized photographs, music, and videos—each with its own special-purpose tool support.^[90] The number of keeping considerations further increases if a person has different e-mail accounts, uses separate computers for home and work, or uses any of a number of special-purpose PIM tools.

Keep less, keep nothing, keep more, keep everything, or keep “smarter”? With respect to some forms of information, people may elect to adopt a “keep less” (or even a “keep nothing”) approach. For example, people can rely on “do nothing” methods of return to web pages—such as searching, auto-completion, inspection of browsing history, or navigating from another website—that require no explicit keeping activity.^[58]

On the other hand, experiencing difficulty in refinding can motivate people toward a “keep more” approach. After a failure to refind a useful website, for example, teachers were reported to have shifted toward a more aggressive strategy of bookmarking “anything” that looked at all useful.^[91] But conscious keeping is costly in time, distraction, and the potential clutter of new items, especially when these end up to be “false positives,” i.e., information judged to be useful but never in fact used.^[4]

Digital memory research (e.g., Tan et al.^[92]) explores an automated “keep everything” or “total capture” approach manifest in one extreme by a full-motion, line-of-sight video recording of daily experiences, second by second.^[45] But the utility of such an approach can be questioned on grounds both practical (e.g., how to selectively access just a portion of the continuous stream?) and psychological (the recording alone does not compare to human memory, and its ability to evoke a person’s actual memory for events may decline with time).^[93] Chapter 6.^[94] Automated keeping also points to a dilemma identified by Lansdale:^[26] without some engagement in the keeping process, people may be much more likely to forget about the information later. Alternatives to “keep everything,” “keep nothing,” and “keep automatically” approaches are ones that help people to “keep smarter,” i.e., to make better decisions concerning future uses of current information.^[4] If people have prepared a clear plan, for example, they are often more effective at keeping relevant information (including a recognition of its relevance) even when the plan and its goal are not the current focus of attention.^[95]

Folders or Tags?

The demise of folders and the file system is a recurrent theme in discussions on the future of information management (e.g., Economist,^[96] Seltzer and Murphy;^[97] see also Jones,^[98] Chapters 6 and 7). There are good reasons for such predictions. A strict folder hierarchy does not readily allow for the flexible classification of information even though, in a person’s mind, an information item might fit in several different categories.^[99] For example, pictures from a conference in Copenhagen can be stored under “Pictures,” “Trips,” “Conferences,” or “Copenhagen.” Why not then, instead of placement in a single folder, allow people to tag these items, i.e., with a tag for each of the categories?

Tagging models of information storage would seem to align more closely with the way people think and might wish to represent their information. Toward the exploration of this possibility, a number of tag-related prototypes for PIM have been developed over the years (e.g., Refs.^[100–103]). A tagging approach has also been embraced in commercial systems, most notably Gmail (as “labels”).

The verdict? The success of tags so far is at best mixed. In one study, Bergman et al.^[104] found that users, when provided with (and informed of) both options to use folders and tags, preferred folders to tags (for both their files and e-mails), and even when using tags, they typically refrained from adding more than a single tag per information item (also a finding in^[105]). Even Gmail, though fundamentally architected to support tagging, has added support for “folders,” <http://googlesystem.blogspot.com/2009/02/gmail-adds-folders-by-improving-label.html>.

Why isn’t the case for tagging more compelling (so far)? Support for the tagging (annotating, labeling) of information items remains basic and fragmented. Many design questions remain. One study, for example, found that users performing tagging had more persistent memories about their information, but that nuanced interaction design was necessary to alleviate the cognitive demand entailed by creating and recalling tags.^[106]

But more fundamental limitations may also apply. Civan et al.^[105] through an engagement of participants in critical, comparative observation of both tagging and the use of folders (through the use of Gmail and Hotmail for the organization of e-mails), were able to elicit some limitations of tagging not previously discussed openly in comparisons between tagging and the use of folders. For example, once a user decides to use multiple tags, it becomes important to continue doing so. A tag such as “Copenhagen,” when not consistently used, becomes much less useful later as a retrieval cue. Conversely, critical discussion can reveal advantages in the use of folders that are not always apparent, for example, that a folder structure can serve as an informal task decomposition and a simple kind of reminder for task completion.^[107]

Just as the answer for the finding (retrieval) of information may be neither navigation nor search but tools that

support an artful combination of both, so to the answer toward better keeping may be neither purely tagging nor use of folders but a tool that artfully combines the best of both.

The Meta-Level: Mapping between Need and Information

Meta-level activity operates broadly upon collections of information (PICs) within the PSI, on the configuration and effective use of supporting information tools, and on the mapping that connects need to information. The daily actions of keeping and finding are largely reactive (i.e., faced with a need, find the information to meet this need; faced with information, identify if and what need it might meet). In contrast, meta-level activity is more proactive. Thus, meta-level activity focuses not on the need or information immediately at hand but on a larger consideration of information collections, supporting tools, and the overall mapping. Alternatively, meta-level activity can be seen to move to a more strategic level in a person efforts to manage their information.

One factorization of meta-level activity makes the simplification that the PSI is one big store to be maintained and organized, and for which, input and output should be managed. People might also benefit from an ability to take measurements in support of various evaluations of the store (e.g., does it have the right information in the right forms, sufficiently current and complete?). This approach leads to the following overlapping kinds of meta-level activities: *maintain and organize*; *manage privacy, security, and the flow of information* (incoming and outgoing); and *measure and evaluate*. Implicit in each of these activity types is an effort to *make sense of and use* the available information. This section takes a close look at each of these meta-level activity types.

But first, note the following:

- Actual PIM behavior we would wish to observe and analyze is likely a combination of meta-level activity, keeping, and finding. The sharing and synchronization of information in a cloud service, such as Dropbox, has elements of *maintenance and organization* (i.e., information is automatically backed up) and *managing for privacy, security, and information flow* (can people trust that their information is secure and safe from snooping? With whom should people share what?). The meta-activity types we consider here might be thought of as vectors—*independent but not necessarily orthogonal from one another—forming a basis for the description of a “point” of actual PIM behavior* (in a large space of possibilities).
- A consideration of meta-level activity makes clear the point that information is not an end in itself but rather a means to an end. Going back to the definition of PIM at this article’s outset, PIM is about managing

information to realize life’s goals and roles. Further, information provides people with a way of managing their limited resources. Here we can consider “META” as an acronym for money, energy, time, and attention. Each of these resources must be managed if people are to be effective in the realization of their goals and the fulfillment of their roles and responsibilities. But people don’t “touch” (manage) these resources directly. People manage via their information. Financial statements tell people whether their expenses are under control and whether they are on track for retirement. Their calendars help them to manage their time. The use of open windows and the tabs of a web browser can be considered as a way of managing attention.

- Further and especially as people’s information is increasingly in digital form, people don’t “touch” (manage) their information directly either but rather via their information tools. Even for information in paper form, people use tools, of course, including staplers, filing cabinets, and their own hands. An investment to select, configure, and learn to use information tools is a critical component of each kind of PIM activity. This holds especially for meta-level activity.
- Finally, as another sense of “meta,” meta-level activity is the “after” activity. Actions at this level such as “spring cleaning” or “cleanup,” notwithstanding their overall importance, are seldom urgent and so easily postponed and avoided.

Patterns of postponement and avoidance are in evidence as we further explore meta-level activity in the remainder of this section.

Maintaining and organizing

Differences between people are especially apparent in their approaches to the maintenance and organization of information. Malone^[31] distinguished between “neat” and “messy” organizations of paper documents. “Messy” people had more piles in their offices and appeared to invest less effort than “neat” people in filing information. Comparable differences have been observed in the ways people approach e-mail,^[56,108–110] e-documents,^[58,62] and web bookmarks.^[62,111]

Across information forms, differences in approaches to organization correlate with differences in keeping strategy. For example, people who have a more elaborate folder organization—whether for paper documents, e-documents, e-mail messages, or web bookmarks—tend to file sooner and more often.^[62] However, people are often selective in their maintenance of different organizations. Boardman and Sasse,^[62] for example, classified 14 of 31 participants in their study as “pro-organizing” with respect to e-mail and e-documents but not with respect to bookmarks; 7 of 31 participants only took the trouble to organize their e-documents.

Diekema and Olsen^[91] found that spring cleaning of information by teachers mostly pertained to physical information rather than digital information. Organization behaviors may also vary based on context. In a study by Capra et al.^[112] university employees reported having more folders for their work e-mail accounts than for their personal accounts.

Several studies have now looked at how the same person manages across different forms of information.^[62,107,113] The following composite emerges:

- People do not generally take time out of a busy day to assess their organizations or their PIM practice in general.
- People complain about the need to maintain so many separate organizations of information and people complain about the fragmentation of information that results. People struggle to organize their information so that they can keep their focus of attention and avoid “getting lost.”^[114–116]
- Even within the same PIC, competing organizational schemes may suffer an uneasy coexistence with each other. People may apply one scheme on one day and another scheme the day after.
- Several participants in one study reported making a special effort to consolidate information in their PICs,^[57] for example, by saving web page references and e-mail messages into a file folder organization or by sending e-documents and web page references in e-mail messages.
- People don’t, in general, have reliable, sustainable (i.e., automatic) plans for backing up their information.^[117,118]

Even if digital forms of information can be integrated, people must still contend with paper forms of information. Paper documents and books remain an important part of the average person’s PSI.^[85] The integration of paper and digital forms of information can be troublesome. In a study of elementary and secondary teachers, for example, Diekema and Olsen^[91] found that the teachers’ dualistic system of digital and physical information was especially challenging; while some teachers tried to standardize their organization schemes across material type, some teachers resorted to digitizing all materials. Others printed out their digital materials so they could be filed with the rest of the paper files.

Managing privacy, security, and the flow of information

We continue with the useful simplification that a person’s PSI is one large store. If maintenance and organization activities are concerned with the store itself and its contents, the activities to manage privacy, security, and, more generally, the flow of information are concerned with the input and output to the store. What do people let in? What do people let out?

Letting the wrong things (information, data) into a PSI or letting the wrong tools access or modify a PSI can, at minimum, be a major hassle (e.g., a need for “disinfection”). At worst, the computer may be hijacked to nefarious ends, and all its data corrupted. Indeed, problems of malware (“viruses,” “Trojans,” “worms”) are endemic. By some estimates, 30% or more of the computers in the United States are infected.^[119] Letting the wrong information out to the wrong people can also be a costly source of trouble—e.g., if credit cards are compromised or worse a person’s identity is stolen.

And yet, the exchange of information, incoming and outgoing, and increasingly in digital forms, is an essential part of living in the modern world. To order goods and services online, people must be prepared to “let out” their credit card information. To try out a potentially useful, new information tool, people may need to “let in” a download that could potentially make unwelcome changes to the web browser or the desktop. Providing for adequate control over the information, coming into and out of a PSI, is a major challenge. Even more challenging is the user interface to make clear the implications for various choices in privacy control and in clicking the “Accept” button for use of services such as Facebook.^[120–128]

Also of relevance are the daily challenges associated with sharing information with others in various social situations ranging from the home, to school, to work, to play, and “at large” (e.g., via open-ended discussion boards on the web). These challenges are further discussed in the section “GIM and the Social Fabric of PIM.”

Measuring and evaluating

Choices are made in support of all the activities described so far. Schemes of organization are selected; strategies, policies, and procedures are adopted; and supporting tools are put in place. People then need to ask, at least occasionally, “Is it (the resulting mapping between information and need) working? Is it helping me to make the best use of my limited resources (money, energy, time, attention) toward meeting my goals and fulfilling my roles and responsibilities? Can it work even better? If so, what should change?”

These questions depend both upon the measurements that can be made and also on the evaluations people must make in cases where measurements (and the underlying objectives they reflect) are in competition with one another.

Actions of measuring and evaluating are often high level and qualitative. For example, as people are driving home from work much later than they’d planned for and with no time nor energy to exercise at the gym, they may reflect on a day of nonstop meetings and interruptions as they ask themselves “What did I *really* accomplish?”

But increasingly evaluations can be based upon numerical data. Questions such as “where does the money go?” or “where did the time go today?” needn’t be only rhetorical.

Increasingly detailed, consolidated data is becoming available to answer these and other questions concerning not only how people manage their resources but also how effectively they're living the lives they wish to live. Detailed financial data can tell people "where" the money is going. Calendars consolidated with activity logs can tell people "where" the time went and much more besides. On which devices? Which applications? Relating to which people or which projects? Involving physical activity as well? Or, conversely, the intake of calories (e.g., a business lunch)? How did physical measures of heart rate, blood pressure, blood sugar levels, etc., vary during these activities?

People's every actions can be tracked, and a digital trace formed. The nearly constant use of computational devices (even as people sleep) creates opportunities to capture additional data about people and their environment for purposes of correlation and, potentially, deeper understanding. Associated issues of privacy are enormous and beyond the scope of this article to address (but see Refs.^[129–131]).

On a more positive side, how can measurements be used to a person's advantage?

The increasing capture (by intention or incidentally) and availability of data in digital form to measure everything from heart beats to gaze duration to affective response give rise to notions of the *quantified self* and *personal informatics*.^[132–137] Definitions of personal informatics (PI) vary. Some would tightly connect PI to enabling devices and applications for tracking (e.g., Li et al.^[138]). But self-efforts to track personal activity—the better to understand and make adaptive changes in behavior—are not new (see, e.g., the description of Benjamin Franklin's efforts at self-observation in Jones,^[139]). Rapp and Cena provide a more flexible definition: "**Personal Informatics** (PI), also known as Quantified Self (QS), is a school of thought which aims to use technology for acquiring and collecting data on different aspects of the daily lives of people,"^[140] p. 613.

PI applications are often affiliated with health information and many times have a dedicated hardware device, such as the FitBit, <http://www.fitbit.com/>. But some examples also include systems that collect personal information over time from a variety of sources to provide upon request more integrative summaries of the many scattered events happening that relate to a person in one way or another. A popular example of this second variety is Mint.com, which collects information from all of one's financial accounts (checking, saving, credit cards, etc.) and summarizes this data into an integrated dashboard.

Personal informatics is properly regarded as a subset of PIM where special focus is given to activities of measuring and evaluating and also to making sense of and using the data collected. For example, Li et al.^[141] decompose a personal informatics system into five stages: 1) preparation; 2) collection; 3) integration; 4) reflection; and 5)

action. The first three stages fit well under the more general activity of measuring and evaluating while the last two stages fit well under the more general activity of making sense of and using information. Not surprisingly, users of PI systems also face challenges to manage for privacy and information flow and to maintain and organize the large amounts of data collected. According to Li et al.,^[142] users face information fragmentation problems comparable to those already discussed in the introduction to this article. More recent work in personal informatics seems to acknowledge a need to think more broadly and to place efforts at "self-tracking" in the larger context of an overall PIM practice.^[134,143,144]

Making sense of and using information

Making sense of information represents another set of meta-level activities operating on personal information and the mapping between information and need. People must often assemble and analyze a larger collection of information in order to decide what to do next. For example, among the choices available in new automobiles (new laptops, new employees, etc.), which will best meet a person's needs? Which treatments to select in the aftermath to surgery for cancer? Does radiation therapy "make sense"? Making sense of and using information means more than just retrieval and comprehension of the information "at hand." A person may look up a budget number and understand that it reads "42" but may conclude that the number doesn't "make sense" (and is possibly a pop culture reference, [https://en.wikipedia.org/wiki/42_\(number\)](https://en.wikipedia.org/wiki/42_(number))) if all other budget numbers are 9-digit numbers beginning with "11-."

Making sense of information is "meta" not only for its broader perspective but also because it permeates most PIM activity even when the primary purpose may be ostensibly something else. For example, people organize information in folders ostensibly to insure its subsequent retrieval but then also as a way of categorizing and so making sense of the information. In the Jones et al. study,^[107] folder hierarchies developed for a project often resembled a project plan or partial problem decomposition in which subfolders stood for project-related goals and also for the tasks and subprojects associated with the achievement of these goals. Similarly, some teachers organize their files by utilizing the structure as established in their curriculum standards.^[91]

Barsalou^[145,146] has long argued that many of a person's internal categories arise to accomplish goals. His research demonstrates an ability of people to group together seemingly dissimilar items according to their applicability to a common goal. For example, weight-watchers might form a category "foods to eat on a diet." Rice cakes, carrot sticks, and sugar-free soda are all members of the category, even though they differ considerably in other ways.

Folders and tags (and piles, properties/value combinations, views, etc.) can form an important part of external

representations, which, in turn, can complement and combine with internal representations (“in our heads”) to form an integrated cognitive system.^[147,148] Finding the right external representation can help in *sense-making*,^[149,150] i.e., in efforts to understand the information. For example, the right diagram can allow one to make inferences more quickly.^[151] The way information is externally represented can produce huge differences in a person’s ability to use this information in short-duration, problem-solving exercises.^[152] Different kinds of representations, like matrices and hierarchies, are useful in different types of problems.^[153–155]

But the effects of an external representation on longer-term efforts to plan and complete a multiweek or multimonth project are less well understood. Mumford et al.^[156] note that, more generally, the study of planning has proceeded in “fits and starts” over the past 50 years and remains underdeveloped. Of special relevance to the study of PIM is the possibility that better support of planning might also, as a by-product, lead to better organizations of the information needed to complete a project.

GIM and the Social Fabric of PIM

Group information management (GIM) as a natural extension to PIM has been written about elsewhere.^[157,158] The study of GIM, in turn, has clear relevance to the study of Computer Supported Collaborative Work (CSCW).^[159]

In legal contexts, it may be useful to treat a corporation as an entity—a “person”—in its own right. A corporation or other organization may have policies, procedures, habits, history, and routines that further give it a collective identity as an entity in its own right.

But in many situations, there really is no group entity operating on its own behalf to manage information toward realization of goals and fulfillment of roles. Rather, there is a collection of individuals. Members of a group may hold in common (more or less) certain goals (whether implicit or explicitly expressed in a charter or mission statement). Members may apportion group roles (e.g., treasurer, secretary, president, etc.), but each member operates as an individual and according to personal interest. In keeping with this article’s topic, therefore, focus is more appropriately on what might be called the *social fabric of PIM*,^[160] Chapter 10. The needs of the individual must be met in any group situation, for example, when engineers need their own private space for working drafts, they are not yet ready to share with a larger team.^[161] On the other hand, group and social considerations frequently enter into a person’s PIM strategy, for example, when one member of a household “keeps” medical test results by passing these on another member of the household who has agreed to maintain and organize medical information for all household members. (And perhaps there is a reciprocal arrangement for financial information.)

Although a collaborative “divide and conquer” approach, where responsibilities are apportioned among the members of a group, can reduce the burdens of PIM, the opposite is frequently the case when people seek to share information collections. People may vary greatly in their approaches, especially to keeping and maintaining and organizing information.^[162] Working together through these issues often entails a delicate negotiation process,^[89,163] as categorization affects each member of the shared space, and the tools used to perform such activities provide no preexisting conventions for tasks like organizing a project’s files and folders.^[164] Some users may customize shared information spaces to meet their own needs, but at the cost of decreasing the intelligibility of that space for others.^[165] These challenges later affect refinding information in shared spaces, where attempts to retrieve information from a shared collection are more likely to fail than when retrieving from a PIC that is not shared.^[166]

As further studies aim to better understand the challenges of sharing and managing information in group contexts, improved software may help to alleviate some of these challenges and facilitate the relevant activities.^[5] Prototypes of such software have attempted to support GIM, for example, by analyzing group activities,^[167] a “silver bullet” solution has yet to be found, however. When faced with the limitations of current software, users often prefer more traditional, ad hoc methods of sharing information, such as the use of e-mail attachments,^[168] to more sophisticated methods supported by tools more explicitly designed to support collaborative work such as the use of web services that support shared folders.^[166,169] In some cases, people will circumvent group-centered approaches even when they are institutionalized.^[170] Therefore, the need for understanding and improving collaborative information tasks is clearly great, and work remains to be done.

The Interplay between PIM Activities

We noted in the previous section that the senses in which information can be personal (i.e., owned by, about, directed toward, sent/shared by, experienced by, or relevant to “me”) don’t provide for groupings of information that are cleanly separated from one another. Rather, these are better seen as different perspectives on one large PSI.

Likewise, activities of PIM can be seen as different vectors of approach, we might say, to a person’s PSI and to the creation, use, and maintenance of a mapping (between need and information) for this space. Any actual action of PIM is likely to be a mixture of each. The interplay between activities of finding and keeping was noted in the previous section. An act of keeping, for example, often engenders acts of finding (e.g., the effort to find a folder where the encountered information should be kept). Likewise, an act of finding frequently engenders ancillary acts of keeping. In the effort to retrieve a file from a personal store, for example,

the person may move (“re-keep”) other files after noticing these are in the wrong folder. And certainly, newly found information beyond simple look-ups (e.g., the weather report or a sports score) must often be kept pending the proper time and place for more careful study.

Interplay is in further evidence as the meta-level of PIM activity is considered. Any actual activity of PIM observed or reported is likely to resist clean categorization as solely one or another kind of activity. People may elect to place project-related files, web references, and even e-mails into a single folder named for the project^[71,171,172] and may elect to keep this folder under a larger folder synced with a service such as Dropbox. The folder may then be shared with others also involved in the completion of the project. Keeping activity? Maintaining and organizing? Making sense of and using information? Managing for the flow of information (and privacy/security)? Yes: all four. And since a cloud service such as Dropbox maintains a log of activity in the folder, we can add measurement and evaluation.

CONCLUSION: CHALLENGES AND OPPORTUNITIES

To summarize, the practice of PIM involves finding, keeping, and several kinds of meta-level activities in an effort to establish, maintain, and use a mapping between information and need. Challenges arise with respect to each kind of activity:

Finding is a multistep process. First, people must *remember* to look. An item is retrieved through variations and combinations of searching and navigation. Navigation and searching each involve an iterative interplay between basic actions of *recall* and *recognition*. Finally, in many situations of information need, people must *repeat* the finding activity several times in order to “re-collect” a complete set of information items in order then to make sense of and use the information at hand.

Keeping is multifaceted. Certainly keeping, like finding, can involve several steps. But the essential challenge of keeping stems from the multifaceted nature of the decisions about information needs. Is the information useful? Do special actions need to be taken to keep it for later use? Where? When? In what form? On what device? With no crystal ball to see into the future, answering these questions is difficult and error prone. Caution is warranted with regard to tool support to “keep everything” or “keep automatically.” The approach can lead to the collection and storage of information that overwhelms even as it falls far short of providing a true “external memory.”

Meta-level activities are important but easily overlooked. Meta-level activities are critical to a successful PIM practice, but rarely urgent. There are few events in a typical day that direct a person’s attention to meta-level activity involving considerations of maintenance and organization, managing privacy, security and the flow of

information, measuring and evaluating, or making sense of and using information in a larger collection. As a result, meta-level activities can easily become afterthoughts.

Researchers also face several challenges in their efforts to develop PIM as a field of study:

Integration to counter fragmentation. In their daily practices of PIM, people must overcome problems of both information overload and information fragmentation. Problems of information fragmentation are often introduced by the very computer-based tools that are meant to help with PIM. The study of PIM itself is often fragmented in similar ways. Many excellent studies focus, for example, on e-mail, other studies on the web, or the management of special forms of digital information (such as digitally encoded songs or photographs). There is a need for integrative approaches both in the study of PIM and in the design and evaluation of supporting tools. The “I” in “PIM” should be for information in all its many forms, paper based and digital, and for a larger perspective that considers the life cycle and impact of information as it is communicated from one person to the next.

Toward more practical methodologies with more practical implications. PIM requires the study of people, with a diversity of backgrounds and needs, over time as they work in many different situations, with different forms of information and different tools of information management. This scope of PIM inquiry brings a need for practical, cost-effective methodologies that can scale. Furthermore, there is a need not only for *descriptive* studies aimed at better understanding how people currently practice PIM (e.g.,^[173]) but also for *prescriptive* studies aimed both at evaluation^[174] and also toward the recommendation of proposed solutions in the form of new, improved tools, techniques, and strategies of PIM.

A kind of “checkbox” methodology—call it “*six by six* (6×6)”—can be devised from the framework described in this article (first described in Jones^[139] and subsequently updated^[11]) with its provision for six senses in which information can be personal 1) controlled by/owned by, 2) about, 3) directed toward, 4) sent/posted/shared by, 5) for things experienced by, and 6) potentially relevant/useful to “me”) and its six-part factorization of PIM activity 1) keeping; 2) finding; 3) maintaining and organizing; 4) managing privacy, security, and the flow of information; 5) measuring and evaluating; 6) making sense of and using information).

For any tool, technique, or larger strategy of PIM, real or proposed, it is important to consider the likely impact on personal information in each of its senses. For example, a “cool new tool” (desktop or web based) that promises to deliver information potentially “relevant to me” (P6, the “6th sense” in which information is personal) may do so only at the cost of a distracting increase in the information “directed to me” (P3) and by keeping too much personal information “about me” (P2) in a place not under the

person's control. Similarly, a tool, technique, or strategy of PIM can be considered for its impact on PIM activity. Tools of personal informatics and digital tracking, for example, may do a great deal to improve "measuring," but if such improvements are accompanied by extra hassles in maintaining and organizing or in managing privacy, security, and the flow information, then the trade-offs may not be worth it.

This 6×6 methodology is not the only approach toward a more thoughtful, systematic design of PIM tools. Bergman, for example, reports good success in the application of a *user-subjective approach* in PIM system design.^[175] The user-subjective approach advances three design principles. In brief, the design should allow the following: 1) all project-related items no matter their form (or format) are to be organized together (the *subjective project classification principle*); 2) the importance of information (to the user) should determine its visual salience and accessibility (the *subjective importance principle*); and 3) information should be retrieved and used by the user in the same context as it was previously used in (the *subjective context principle*). The approach may suggest design principles that serve not only in evaluating and improving existing systems but also in creating new implementations. For example, according to the *demotion principle*, information items of lower subjective importance should be demoted (i.e., by making them less visible) so as not to distract the user but be kept within their original context just in case they are needed. The principle has been applied in the creation of several interesting prototypes.^[176-178]

In a similar vein is the research by E. Jones^[179] identifying five factors that determine whether a promising new system (tool, technique, and strategy) of PIM will be successfully adopted:

1. *Visibility*—More generally, do users notice the system and remember to use it?
2. *Integration*—Does the system connect and work well with what the user already has in place?
3. *Co-adoption*—Is it necessary for others to use the system as well? (Lack of co-adoption is a major source for failure in CSCW applications.^[180])
4. *Scalability*—Will the system still work over time and especially as the amount of information continues to increase?
5. *Return on investment (ROI)*—After the hopeful enthusiasm with which a system is initially embraced has waned, the system has to prove its value and that the costs of its use are more than compensated for by benefits.

The trouble with the adoption of PIM systems is twofold: 1) some may be discarded prematurely before the daily habit of their use has been established (e.g., for lack of visibility or integration); and 2) the problems with other

systems (e.g., lack of scalability or ROI) are apparent only much later after a system has been deeply embedded in a person's overall practice of PIM, making its removal a costly hassle. Consider, for example, a "perfect" folder organization that turns out to be too much trouble to maintain but can't be undone without many hours of reorganization.

More recently, the notion has been advanced that tools, techniques, and strategies of PIM might be assessed for their ability to increase or reduce the "clerical tax" people pay as they manage their information.^[93] What is the impact on the time spent in clerical, mechanical actions of PIM (think filing paper documents in a vertical filing cabinet), and how much time remains for the more fun, creative aspects of working with information? The utility of such an approach will depend upon the development of more detailed methods for reliably, effectively "assessing" the clerical tax.

Finally, are efforts to engage the user in active discussions (possibly mediated by the web) directed toward the evaluation and even the design of PIM systems? The use of participant observation is well established in fields such as sociology and anthropology (see, e.g., Jorgensen^[181]). But here we might talk instead about the *observant participation*, i.e., explicitly tasking a participant to reflect upon a PIM system, the good and the bad, either in a single session or over an extended period of time. The use of diary methods of data gathering is well established (e.g., Czerwinski et al.^[81]), though motivating people to consistently record their thoughts can prove challenging and reminders can prove intrusive or, worse, impact the data gathered.^[182]

Two recent efforts of *observant participation* are worthy of further mention. Civan et al.^[105] engaged users in a within-subjects comparison of tagging (labeling) vs. the use of folders as a means of organizing e-mails. Participants experienced each condition (via actual web-based versions of Hotmail and Gmail as these were offered in 2007/2008) in an ordering counterbalanced across participants. After each condition (each lasting for 5 days), participants were interviewed using an open-ended set of questions to assess their experiences of and reflections on the condition just experienced (i.e., use of folders vs. tags for organization of information). The study provided a very useful set of considerations and some unexpected drawbacks in the use of tags (e.g., with the freedom to tag items in several ways comes the potential tedium of then consistently using multiple tags for *_every_new_* item). A second method—following a Delphi approach^[183]—shows great promise for better understanding various current practices of PIM and assessing which to "recommend" and "advise against."^[184]

Observant participation relates to but is distinct from approaches in *participatory design*^[185,186] wherein that attempt to "actively involve all stakeholders (e.g., employees, partners, customers, citizens, end users) in the design process to help ensure the result meets their needs

and is usable,” http://en.wikipedia.org/wiki/Participatory_design. Methods of observant participation such as those described previously are best seen as exploratory heuristics to gather pros and cons and considerations in the use of one tool, technique, system, or strategy of PIM vs. another. The participant observer approach to PIM can be traced at least back to Malone’s^[31] work (with only 10 participants). In his “methodological note,” Malone writes, “Sometimes . . . carefully controlled studies or more extensive naturalistic observations are suggested by the insights obtained from exploratory observation, and these are certainly worth performing. In other cases, the needs for designing systems (or time and budget constraints) do not justify other studies” (p. 101).

How to protect the privacy and security of personal information? The more complete the digital records of personal information, the more completely a person’s identity can be stolen. New PIM tools—especially those aimed at information capture—must be accompanied by new levels of information security and privacy.^[127]

Other questions arise for PIM-related tools and technologies:

How to keep e-mail from being spoiled by its own success? E-mail messages are easy and free to send—good for us; good for spammers too. E-mail is used for tracking tasks, storing documents, and saving contact information. It was designed for none of these. People may feel like they are “living” in their inbox.^[187] But are they doing the things they really want to be doing? Why should all incoming correspondence go into one undifferentiated inbox? E-mail filters to sort have their own problems (e.g., that people forget to look in the sorting folders later). Research efforts have explored ways to better situate e-mails and other correspondence in larger contexts involving tasks, projects, and “places” of collaboration (e.g., Refs.^[188–190]). People are also making ad hoc use of alternatives to e-mail such as Facebook groups.^[191]

How can search get more personal? Search has application to PIM both as an interaction and as an underlying technology. Search as an interaction supports finding and refinding and also other PIM activities such as keeping, maintaining, and organizing. Search as technology, including the analysis and indexing of information, can be seen more broadly as a way of “mining” a PSI toward a wide range of personalized support.^[51,98,192,193]

How can information convergence bring information integration? Information tools increasingly let people work with their information anytime and anywhere. This has increased the amount and diversity of information collected. Thoughts of laptops, smartphones, or tablets as a point of convergence for information and practices of PIM are inspired by the ongoing rapid pace of technical developments in hardware capacity, miniaturization, and integration.

Thoughts of the web as a point of convergence are also inspired by hardware advances supporting, for example,

increases in bandwidth (especially along the “last mile” to private homes) and storage capacity. But equally, the web is a point of convergence for its basic ability to connect, nearly instantaneously, person to person and person to information, no matter where these are in the real world, no matter what the physical distances. But convergence does not equal integration. Web-based and portable computing are still in their infancy, and new opportunities for convergence and integration are still being created (e.g., watches, wearables). The field of PIM has a special opportunity to guide development in these new areas.

As researchers study and strive to improve PIM, it is important never to lose sight of the “personal” in PIM. People manage information neither for its own sake nor for the joy of managing. PIM is a means to an end. A person manages information in many forms, ranging from appointments of a digital calendar to paper checks of a check book, in order to manage life’s resources—money, energy, attention, and, especially, time. A person manages information as a means toward the fulfillment of a life’s important goals and precious roles.

Peru: Libraries and Library Science

Sergio Chaparro-Univazo

Graduate School of Library and Information Science, Simmons College, Boston, Massachusetts, U.S.A.

Abstract

Libraries in Peru have been the subject of tremendous evolution. The Spanish influence brought the concept of libraries and the printing press, but it was not until the twentieth century when librarianship in Peru was established as a discipline and profession. Library education has grown rapidly and the post-Internet times have produced a very dynamic information society that still requires more consistent library services.

INTRODUCTION

Located on the western rim of South America, Peru is bordered on the north by Colombia and Ecuador, on the east by Brazil, on the southeast by Bolivia, on the south by Chile, and on the west by the Pacific Ocean. Its geography varies from the arid plains on coast to the spectacular Andes Mountains and the lush tropical forests of the Amazon Basin. Estimated at 29,180,900 (July 2008), the population of Peru is multiethnic: Amerindian 45%; mestizo (mixed Amerindian and white) 37%; white 15%, black, Japanese, Chinese, and other 3%. The government is a representative democratic republic divided into 25 regions (Fig. 1).

HISTORICAL BACKGROUND

Libraries in Perú have a long history that started with the Spanish conquest and the introduction of the printing press in the sixteenth century. During the Spanish domination there was a strong impetus to create private and monastic collections, intended mostly to indoctrinate the indigenous populations. The Inca and Pre-Inca cultures did not have an alphabet, but that did not preclude them from achieving extraordinary development. Based on oral traditions and quipus as a way of translating words, they built up one of the most important cultures in the southern hemisphere. The Inca Empire also gave birth to the most important and wealthiest Spanish possession in the Americas—Peru. During the period when Peru was a colony of Spain (from 1535 to 1824) monastic and private collections were developed to instruct the Indians with Christian doctrine. The Franciscan Monastery of our Lady of Ocopa was a good example of a large monastic collection of around 20,000 volumes.

Some of the Spanish conquerors carried personal libraries with them, and during the expansion of the Spanish viceroyalty reading spread among clergyman, lawyers, and a growing student population. The book trade also developed, but

most works were imported from Europe. However, the sixteenth century was critical for the development of a book culture and printing thanks to Antonio Ricardo and his printing Press in Lima. The Jesuits gave a space to Antonio Ricardo at the Colegio de San Pablo to install his printing press which was set up as early as 1584. Ricardo's first book was the *Doctrina Christiana* and it was published in three languages: Spanish, Quechua, and Aymara.

The Inquisition also played an important role in its censorship role of heretic literature. The Holy Office of the Inquisition in Spain controlled the importation and publishing of books. Efforts to counteract that control were sometimes made by individuals who collected private libraries that then emerged as a sort of "counter culture" space because they held materials that were listed as banned in the *Index Librorum Prohibitorum*. However, the owners of these private libraries that contained banned materials risked being prosecuted. The French Enlightenment and the Bourbon dynasty of 1701 brought new impetus to those private collections.

Special mention needs to be made here about the important role that universities played in the creation of library collections, encouraging reading and developing the culture of the viceroyalty of Peru. The Universidad Nacional Mayor de San Marcos (UNMSM) was founded in 1551. When the Jesuits were driven out of Peru in 1768 their major collections at the Colegio de San Pablo were given to UNMSM. Around this time we find the first attempts to promote some sort of public librarianship. Around 1778 UNMSM suggested that rooms at the Colegio de San Pablo be offered to the public for public reading.

It was mainly during the independence period of 1821–1824 that the concept of public libraries emerged in the new republic. The National Library was created by Don José de San Martín on September 17 of 1822. At the time of its inauguration, the library held around 112,256 volumes. Most of its holdings came from citizens' donations, from the University of San Marcos, and even the private collection of Don José de San Martín. During the Pacific

Source: CIA World Factbook. <https://www.cia.gov/library/publications/the-world-factbook/geos/pe.html>

War in 1881 the National Library was invaded and decimated by the Chilean army and its collections ransacked. Of the 56,000 volumes only 738 remained after the Chileans left. Ricardo Palma, a writer and scholar, who was later famous for his *Tradiciones Peruanas*, rebuilt the National Library from the ruins. Palma's task was monumental and symbolizes perhaps one of the most challenging reconstruction tasks of a library in world history. When assigned to the job by President Iglesias, he asked the president if he was going to be a "mendicant librarian," the President's answer was yes. He then got the nickname *the mendicant librarian* (el bibliotecario mendigo). International donations were essential, and many donations were received through Palma's contacts in the South American region. Palma even asked the President of Chile for the restitution of some collections. Contrary to what we might think, his wishes were acknowledged. The National Library reopened on July 28, 1884.

RECENT HISTORY: THE POST-WAR YEARS

Library education and professionalism in Peru were given an impetus by the events that happened around 1943. The library profession itself took its first major step with the appointment of Jorge Basadre (1905–1980) to rebuild the Biblioteca Nacional (National Library) devastated by a fire in 1943, and the foundation on June 23 of the same year of the Escuela Nacional de Bibliotecarios (National School

of Librarians). Basadre had been exposed to international librarianship and had a strong interest in building and strengthening the library profession. For example, he participated in professional exchanges with North American advising committees such as the American mission of 1943, which included Dr. Keyes D. Metcalf, Director of Harvard libraries and President of ALA; Lewis Hanke, Director of the Spanish Foundation of the Library of Congress; and Wilmarth S. Lewis, Director of Yale University Libraries. Basadre's push brought a new wave of library publications. Important library publications of those years were the *Boletín de la Biblioteca Nacional*, *Fénix*, and the publication of the *Anuario Bibliográfico Peruano* in 1945. Basadre's influence was also noticeable in the new conceptualization of public libraries and their role in society. He was responsible for the promotion of the popular libraries and the decree of May 25, 1947, Law 10847 that supported taxation for public libraries.

Basadre's interest in public librarianship later stimulated the development of some important public libraries like the Ricardo Palma in the district of Miraflores and the ones in Surco and San Isidro. The post-World War II era saw an increasing concern in society about the need to strengthen and solidify municipal and public libraries, two institutions that targeted similar kind of patrons. Municipal libraries are administered by the municipal government, and by 2004 there were 1080 municipal libraries in Peru. Even though such libraries are numerous, their work is very much limited by the lack of an adequate funding, and their overall development has been hindered

by the lack of a coherent vision concerning their role in society. One of the oldest municipal library is the *Callao Municipal Pilot Library* founded in 1936. The first bookmobile in Perú was inaugurated in 1957.

School libraries are present in most private schools, but their quality varies depending on their funding and administration, which is based on tuition and the school policies. The earliest academic libraries in Peru date from the sixteenth century around the time of the founding of the oldest University in the Americas, the *Universidad Nacional Mayor de San Marcos* on May 12 of 1551 by decree of Charles V. Numerous new academic institutions have proliferated since then. Among the oldest public academic institutions are the *Universidad San Antonio Abad* (1692, Cuzco), and the *Universidad Nacional de Trujillo* (1827), and the *Universidad de San Agustín* (1827, Arequipa). There are around 98 public and private universities in Peru, and most of them have academic collections. The quality of their collections however is very uneven. Some recent efforts toward more digital collections have been made and academic libraries were among the first institutions that developed digital resources and supported widespread use of the Internet. One of the leaders in this area was the *Universidad Peruana de Ciencias Aplicadas*, which began to develop digital resources in the mid-1990s. In terms of collections (print and online), among the most important are the collections from the UNMSM (public) and the Peruvian Pontifical Catholic University (private), Cayetano Heredia, and the Pacific University (private).

Other important libraries that are not necessarily public in terms of access but contain important collections are those of foreign institutes such as the Alliance Francaise, the Instituto Británico and the Instituto Cultural Peruano Norteamericano (ICPNA). The library of the Lima Art Museum, the *Manuel Solari Swayne Library*, holds around 10,000 volumes, and was created in 1986. The Getty foundation has supported its acquisitions program.

LIBRARY EDUCATION AND PROFESSIONAL ASSOCIATIONS

The *Escuela Nacional de Bibliotecarios* was transferred to the UNMSM as a university program, and its name changed to *Escuela Académico Profesional de Bibliotecología y Ciencias de la Información*. This national school and the Library School at the Peruvian Pontifical Catholic University (PUCP), established under the sponsorship of the British Council in 1990, are the only library schools in Peru.

In recent years research in library and information science has developed, as is evident in the production of professional journals such as *Alexandría*, *Bibliodocencia*, *Biblios*, *Bibliotecólogos*, and *Infobib*. Some of these journals are peer reviewed and reflect the interest of an increasing professional and research community to

improve professional knowledge. The existence of associations is also another sign of the interest of professional librarians in expanding their knowledge and professional expertise. Among the most important associations are the *Colegio de Bibliotecólogos del Perú* that followed the *Asociación Peruana de Bibliotecarios* created in 1945.

THE NATIONAL LIBRARY

On March 27, 2006, the Peruvian National Library inaugurated a new building, which also houses the *Centro Bibliográfico Nacional*, which is in charge of national bibliographic control through legal deposit (the current Legal Deposit Law 26905 was passed in 1997). The national bibliographic center also carries out other tasks such as the registration of all bibliographic materials at the national library, implementation of technical processing of Peruvian materials, and the creation of bibliographies of important Peruvian authors. The National Library is a member of the *Asociación de Bibliotecas Nacionales de Iberoamérica*. In many ways, the move to a new building has also enhanced the visibility of the National Library in Peruvian society, but much more work around public librarianship needs to be done.

MODERN CHALLENGES

The modern challenges are related to building a stronger municipal/public library system with adequate funding, the improvement of the public library system that still is administered by the National Library, and the provision of Internet access in broadband to the academic and special library sector. In addition, environmental concerns and the importance of the indigenous population in Peru have prompted discussions about librarianship that are centered around enhancing the development of library services for underserved populations and on the implementation of projects that target their information needs. Some projects revolved around The *Centro de Documentación e Información del Instituto de Investigación de la Amazonía Peruana* (IIAP) and the “*Red de bibliotecas fluviales del Alto Marañón*.” Rural librarianship and its growth is also another area that librarianship needs to integrate more consistently into the progress and development of the indigenous information needs.

Academic libraries in Peru are now facing important changes and challenges with regard to database access, use of open access software, design of OPACS, and the integration of their services. Most academic libraries utilize closed stacks and that affects the circulation and the characteristics of the services they provide.

Special libraries, such as the ESAN (Escuela Superior de Administración de Negocios) or Inrena (Instituto Nacional de Recursos naturales), are important examples of the diversity of information resources available now. Peru has a tremendous diversity of natural resources and

land, and given the current interest on environmental issues, has paid attention to creating information networks and virtual libraries concerning natural and agricultural resources. For example, Rebiapi is a portal of agricultural information. The *Biblioteca Agrícola Nacional* is located at the *Universidad Agraria* in la Molina, a district of Lima. Public health has also been an important focus for the development of information services in Peru. With regard to public health, special mention needs to be made of REPEBIS, *Red Peruana de Bibliotecas en Salud*, which also produces the *Biblioteca Virtual en Salud*.

Librarians in Peru began to participate in the trend toward the development and promotion of Internet use for education, scientific information, and libraries when Red Científica Peruana (RCP, the Peruvian Scientific Network) was created in 1991 as a nonprofit organization. RCP developed an innovative way of offering Internet access to citizens using public computer terminals. RCP was innovative in many other ways as well, implementing the first satellite connection to the Internet, the first use of listservs, the first Web site, and the first electronic newspaper, all without government subsidies. In many ways the RCP introduced the value of the Internet as an educational tool to Peruvian society.

CONCLUSION

In summary, librarians in Peru are currently working

- To improve the access and quality of their collections, particularly in academic areas.
- To design and implement innovative efforts to build up information resources for indigenous populations.
- To expand special libraries.
- To strengthen rural librarianship.
- To provide better access services through broadband.

Libraries will not be able to evolve without dependable electronic access services and discounted access rates that need to be discussed in the context of wider information policies. For that reason, advocacy on the part of the library world is necessary as is awareness and education about ways to advocate for library funding and tools. Another challenge comes from the lack of a coherent and supportive policy on the part of the government regarding the book trade and publishing, since this is still the main source supplying materials in library collections. High costs and widespread piracy are factors that make the production of books in Peru difficult.

Libraries are still working hard to find a permanent space in the every day life of the Peruvian citizen. Funding and professional expertise remain a challenge for most of the small public/municipal and academic libraries that survive on donations and small budgets. The last 10 years of post-Internet development have stressed the importance of the library, but the improvement of the quality and promotion of the services is a major task yet to be done.

Philosophy and the Information Sciences

Jonathan Furner

Department of Information Studies University of California, Los Angeles, Los Angeles, California, U.S.A.

Abstract

Philosophy and the information sciences intersect in various ways. Philosophical approaches to the study of information and information-related phenomena focus on metaphysical, epistemological, and ethical questions; philosophical approaches to the study of the information sciences focus on methodological issues. Metaphilosophical questions may also be asked about philosophy of information and about philosophy of the information sciences.

INTRODUCTION

There are several scholarly activities or practices that coalesce at the intersection of, on the one hand, philosophy, and on the other, the information sciences. The aim of this entry is to distinguish among some of these practices, and to assess their significance, both for philosophy and for the information sciences. In particular, a distinction is drawn between philosophical questions asked *in* the information sciences and philosophical questions asked *about* the information sciences, and the goals and subject matter of *philosophy of information* and *philosophy of the information sciences* are described. This distinction is made in the spirit of conceptual clarity, rather than to reflect a division that is rigorously respected in actual scholarly practice: people interested in philosophy are likely to be interested in questions of all of these kinds.

To some who work in the information sciences, the questions that are posed in philosophy may seem like “meta-questions,” in the vague sense that they are after, later, beside, beyond, or above other questions to which answers are required more immediately, directly, or pressingly. Since categories of meta-questions are commonly identified as forming core components of the contents of fields at the intersection of philosophy and the information sciences, it is worth taking some care to clarify several different conceptions of the qualities that distinguish meta-questions from their non-meta counterparts.

Philosophy of Information as a Meta-Field

Encountering the information sciences for the first time, we might wonder what they are all about. We might want to ask, for example, What is this thing they call “information”? In what way does it exist? What kind of thing is it? Of what fundamental category of things is it an instance? What is its essence? What are its properties? What are the necessary and the sufficient conditions some thing must

satisfy for it to be counted as information? Questions about the mode of existence and the basic nature of different kinds of things are questions that are asked in the branch of philosophy known as *metaphysics*, i.e., philosophy of being. They might be treated as meta-questions simply because they are foundational questions about the fundamental nature of the things in which we are interested. The simple form of questions of this sort belies the difficulty of providing answers that survive all challenges.

The questions just listed are questions about a phenomenon—information—that is a core component of the subject matter of the information sciences, and they are questions that are commonly addressed both in introductory texts^[1] and in more advanced treatises^[2] in the information sciences. Their philosophical nature (of which more will be said below) and their focus on the phenomenon of information are individually necessary and jointly sufficient conditions of their also being considered part of a branch of philosophy known as philosophy of information, and they are questions that are commonly addressed both in introductory texts^[3] and in more advanced treatises^[4] in that field, too. Philosophy of information is discussed in a separate section below (headed “Philosophy of Information”).

Meta-Questions about the Information Sciences

We may distinguish questions that are raised *by* or *in* a discipline or field of inquiry, or in a group of fields like the information sciences, from questions that are *about* that field or group of fields. Questions of the second kind might include questions about the subject matter of the field, its scope, its purposes and/or goals, its methods, its relationships to other fields and to other activities, and its usefulness, worth, or value. These are meta-questions about the field *as a field*, i.e., questions that are raised by studies *of* the field, rather than by studies *in* the field.

Sometimes it is considered that it is worth keeping the second-order questions that relate to a given field separate

from their first-order cousins, and treating the second-order questions collectively as a discrete “meta-field.” Sometimes such meta-questions are identified as being philosophical questions simply in virtue of their second-order status, and the aggregate of such questions is what is construed as the philosophy of field x —even though it might be unclear as to what is strictly *philosophical* about any given meta-question. More commonly, however, the history, sociology, and politics of any given field x are identified as meta-fields that are distinguishable from the philosophy of field x . Meta-questions about the who, what, where, when, and why of the information sciences are the kinds of questions that are asked by sociologists, historians, and political theorists: What is the subject matter of the information sciences as they have been practiced at different points in history, and in different social contexts? What are the characteristics of the social groups whose members work on the information sciences? What motivations have people had for devoting time and other resources to the study of information and related phenomena? Why ought people to be interested in information?

Philosophy of the information sciences may then be distinguished from the history, sociology, and politics of the information sciences as the meta-field in which distinctively philosophical questions are posed (and philosophical answers attempted) about the information sciences. We might ask, for example, What is the nature of the information sciences? In what essential respects do they differ from other areas of inquiry? Questions of this kind are different from questions of the kind asked in Philosophy of Information (as defined above), in the sense that they do not arise *in* the information sciences and are not answerable by doing information science. Indeed, philosophy of the information sciences—like, for instance, philosophy of the biological sciences—may readily be construed as a branch of philosophy of science. Philosophy of the information sciences is discussed in a separate section below (headed “Philosophy of the Information Sciences”).

Philosophy of Philosophy as a Meta-Field

There is another, narrower sense in which a field of inquiry may be identified as a meta-field. This is the sense in which philosophy of philosophy (also known as *metaphilosophy*) is considered a meta-field. One important characteristic of metaphilosophy is its reflexivity. A *reflexive* meta-field is one that comprises the x -like study of x —for example, the philosophical study of philosophy;^[5] or the information-scientific study of the information sciences.^[6] Indeed, it is possible to ask philosophical questions about philosophy of information and about philosophy of the information sciences: about, for instance, how they ought to be done. Again, questions of this kind are different from questions of the kind mentioned in the previous paragraph, in the sense that they

are questions *about* philosophy of those particular kinds, rather than questions that arise *in* philosophy of those kinds or that are answerable by doing philosophy of those kinds. The possibility of a productive metaphilosophy of information and of the information sciences is briefly revisited in the section below on “Meta-Questions about Philosophy.”

The Information Sciences as Meta-Fields

Sometimes the information sciences themselves are taken to form a group of fields of inquiry that are each, in a unique and significant way, concerned to answer meta-questions about other fields.^[7] In one important sense, much of the subject matter of library and information science, for instance, consists of other fields of inquiry: the objects of inquiry are those other fields. Studies of the structural relationships among and within different fields (for example, studies of the frequency with which, and the ways in which, authors in field x cite authors in field y), of the information needs and uses of people working in and between different fields, of the processes by which information is produced, organized, retrieved, communicated, and applied in different fields—these can all be considered as exemplifying a meta-field, in the sense that the subject matter of that field is made up of other fields. Other fields of inquiry that are regularly identified on this basis as meta-fields are education and, indeed, philosophy of science. Introductory characterizations of the information sciences and of philosophy are respectively provided in sections below on “The Information Sciences” and “Philosophy.”

Information Meta-Studies as a Meta-Field

Sometimes it is enough that a particular study involves or requires comparative evaluations of alternative theories, models, or conceptual frameworks, or simply that it consists of an overview or summary of multiple sets of previously published data, findings, or conclusions, for it to be categorized as a meta-study. Examples certainly exist of named meta-fields that are devoted to classifying and assessing theoretical frameworks: recently emerging subfields of philosophy include meta-ethics, metaontology, and metametaphysics. By analogy, we might imagine a field called “information meta-studies” that comprises comparative evaluations of alternative theories in the information sciences. Such work is not considered further in this entry.

Personal/Professional Philosophies of Information Work

Similarly, one sense of “philosophy” that will not be covered further in this entry is the one that people mean when they talk about their (or their institution’s) personal or

professional “philosophy” of information work, scholarship, or research. It is in this sense that people sometimes talk about *having* a philosophy, which is different from the sense in which philosophers *do* philosophy. Talk about the philosophy that one has, in this sense, is typically equivalent to a statement of one’s long-term or fundamental goals or mission, or a statement of one’s basic or most strongly held values. Having a knowledge of professional ethics is not a necessary prerequisite for making statements of goals or values. Nevertheless, study of professional ethics can provide suggestions of values to hold that are in line with others’, and can provide knowledge of ethical principles that can aid choice among values. Information ethics is commonly construed as a branch of philosophy of information, but mere statements of values (which may or may not result from the study of information ethics) are not usually conceived as contributions to philosophy—at least, not in the strict sense of “philosophy” used by most philosophers.

THE INFORMATION SCIENCES

Before embarking on any further examination of the intersections between them, it would be useful to be able to draw on characterizations both of philosophy and of the information sciences—ideally by considering suggestions of the necessary and sufficient conditions which must be satisfied before identifying any given work as a contribution to either philosophy or the information sciences. Some would say that to define either field would itself be to engage in philosophy; so maybe if we briefly indulge in an attempt to define the information sciences, it will become partially clear, through example, what philosophy of the information sciences is.

The goals of people engaged in any field of inquiry typically include not just fame, fortune, and happiness, but also the production of knowledge about (or, perhaps, the shedding of light on, or the making of sense of) a particular part or aspect of the world, through the construction of theories and explanations and the interpretation of meanings and understandings, and the application of that knowledge in a way that changes the world for the better in some respect. What is the particular part or aspect of the world with which the information sciences, especially, are concerned? In other words, what is the subject matter of the information sciences? What are they *about*?

The simplest answer, of course, would be that the information sciences are about information. Perhaps this answer could be extended relatively uncontroversially to include, as the subject matter of the information sciences, certain phenomena that are thought to be closely related to information, and the ways in which people interact with information and with information-related phenomena. Even taking this short step, however, would likely dismay some who would prefer to treat an emphasis on people’s interactions with

information as merely one example of a range of approaches that may possibly be taken to the study of information, each of which is associated with a number of pre-suppositions about the nature of information and its role in the world. In any case, such a barely extended answer would require augmentation in several respects before it could provide real insight into the nature of the information sciences. Helpful additions would include: a definition of information; enumeration and description of information-related phenomena, and indication of the respects in which and strengths with which they are related; and enumeration and description of ways in which people interact with information and with information-related phenomena.

Definitions of Information

Different conceptions of information have attracted consensus to different degrees in different communities. The multiplicity of current conceptions partly reflects the lack of agreement among communities on a prioritization of the desiderata that a conception should satisfy. In particular, the outlook for those who would hold out for a “one size fits all,” transdisciplinary definition of information is not promising. It is possible, nevertheless, to identify a number of general categories or families of conceptions of information that have proven useful in relatively broad ranges of contexts.

1. A *semiotic* family. In conceptions in this group, distinctions are typically made on the one hand between: 1) real-world states, facts, or situations; 2) mental representations of those situations; and 3) linguistic expressions of those representations, and on the other between tokens and types, of situations, representations, and expressions—forming a model (of the relationships between reality, thought, and language) of the kind roughly depicted in Fig. 1.^[8] Each distinct conception of information in this family equates information with the content of a different cell in the model. For many, the crucial decision will be to choose between a conception of information-as-signal (Buckland’s “information-as-thing”), and one of information-as-message (Buckland’s “information-as-knowledge”), but conceptions of information as the stuff of which real-world states are actually composed are not rare.^[9–11] *Objectivist* versions of the popular view of information-as-message assert that information resources (texts, sentences, words, characters, bits) “contain” information, that information resources “have” meanings, that “the” meaning of an information resource is discoverable by all, and that whether a given information resource has a given meaning is an objective matter. *Subjectivist* versions recognize, in contrast, that information resources do not “have” meanings, but that different meanings are assigned to the same resource by different people at different

	Real-world situations: Information as reality	Mental representations: Information as message, meaning, knowledge, image	Linguistic expressions: Information as signal, vehicle, data, document, thing
Tokens / Particulars	States of affairs	Thoughts	Utterances
Types / Universals		Propositions	Sentences

Fig. 1 A semiotic model of the relationships between reality, thought, and language.

times, and that “the” conventional meaning of a given resource is a matter of intersubjective consensus.^[12]

2. A *sociocognitive* family. In conceptions in this group, the emphasis is on action and process, and especially on processes by which people become informed or inform others. Information is conceived either as the act that causes a change in a person’s mental state or internal “knowledge structure,” or as the event in which such change takes place.^[13,14] Different theorists have different views about the respective strengths of different kinds of influence on the effects of the informing act. Adherents to a *physical*, systems-oriented paradigm that is based on a literal reading of Shannon’s mathematical theory of communication^[15] ascribe no role to the intentions of the individual person, whereas proponents of the *cognitive*, user-oriented viewpoint allow that the nature of the change wrought on an individual’s mental model or image of the world by a given informative act depends at least partly on the prior state of that individual model. The main theme of the *sociological*, community-oriented paradigm is that individuals’ images of the world are shaped at least partly by those individuals’ understandings of others’ views, while the *cultural*, discourse-oriented paradigm derives from a recognition that the world itself is socially constructed in a strong sense, i.e. as a direct result of people talking about it.^[16]
3. An *epistemic* family. Conceptions of information in this group are developed with the aim of providing an account of the properties that an information resource must have if the beliefs that are generated upon interpreting the content of that resource may be said to be justified. These are conceptions of information-as-evidence.^[17] On the relatively few occasions on which information is taken seriously in the philosophical literature as a category to be distinguished carefully from knowledge, it is typical for “information” to be equated roughly with “evidence,” and for the primary question about information to be understood as the question about what the evidence must be like to justify a given belief-that-*p*, and thus to qualify that belief (if it is one that is true) as knowledge. Theories of *semantic information* (also known as informational semantics) have

been developed that propose probabilistic methods of evaluating the informativeness of evidence as the degree to which it provides warrant or grounds for believing-that-*p*. Such methods typically involve calculating the unexpectedness of the observed evidence given the probabilities of occurrence of all the possible alternatives. In this sense, they derive from Shannon’s “information theory” (i.e., the mathematical theory of communication), and form the core of the branch of philosophy of knowledge known as *information-theoretic epistemology*.^[15,18] The project that Floridi calls “Philosophy of Information” (PI) is a major contribution to this subfield.^[19]

Information-Related Phenomena

Different kinds of phenomena may be considered to be “related” to information (howsoever information is defined) in different ways. Some phenomena may be seen to be related in virtue of their being the same kinds of things as information. Conceptions of information-as-message, for example, tend to be held at the same time as conceptions of knowledge-as-message, in which case knowledge and information are said to be related in the sense of their being identical. On the other hand, in such conceptions, information is distinguishable from data on the basis that information is the content or meaning of data: here, information and data are related, not in virtue of a conceptual identity, but in virtue of one (information) being a kind of property of the other (data). Similarly, authors, indexers, and searchers are related to information in respect of their being agents that are involved in the creation, representation, and seeking of information resources; libraries, archives, and museums are related to information in respect of their being institutions that are involved in the preservation and provision of access to collections of information resources; aboutness and relevance are related to information in respect of their being relations that structure networks of information resources; and so on.

Kinds of Human–Information Interaction

Lists of information-related phenomena are necessarily endless, and of limited utility: what is potentially more

interesting from a philosophical perspective is the structure of fundamental categories of phenomena (e.g., objects, properties, relations, agents) developed by the listmaker. Similarly, no list of the kinds of things that we might imagine people wanting to do to, with, or through information could be exhaustive, no matter what definition of information is accepted. But taxonomists of information-related actions or events commonly adopt a framework that is loosely based on the notion of an information life cycle, whereby information resources (if not the meanings attributed to those resources) are assumed to have a concrete existence in space–time, and to be subject to change and to processes of cause and effect. Within such a framework, distinctions are often made between the following categories of actions or events: production, creation, and generation; reproduction; preservation and storage; representation, description, cataloging, registration, and documentation; organization, arrangement, and classification; transfer, communication, retrieval, and provision of access; search, discovery, and seeking; evaluation and appraisal; use and application; and destruction.

The Scope of the Information Sciences

The aggregate scope of the fields collectively labeled “the information sciences” or “information studies” is very broad. Any precise delineation of that scope will depend partly on the sense in which “information” is understood. Different authors, working with different conceptions of information, continue to define the scope of the information sciences in very different ways. There nonetheless appears to be a reasonably stable consensus about the identity of those areas of concern that collectively form a central core, in contrast to other areas that are typically recognized as more peripheral. One formulation of the goals of projects associated with this core might run as follows:

1. Understanding the nature of information, of information-related phenomena, and of human–information interaction.
2. Understanding the identities, purposes, motivations, intentions, needs, desires, and actions of people engaged in interaction with information.
3. Designing and building systems, services, and structures that help people to meet their goals when interacting with information.
4. Developing and administering policies and institutions that enable and/or constrain people’s interactions with information.

Within this framework, it is possible also to distinguish between a conception of the information sciences (or of some of its components) as essentially descriptive,

devoted to the construction of theories that explain how information-related events actually do occur in the real world and why real people actually do act and think in the ways that they do, and a conception of the field as essentially prescriptive or normative, devoted to the specification of the ways in which things should happen and the ways in which people should act.

In pursuing projects of these kinds, information scientists draw on theories and practices developed in many overlapping fields of inquiry, not least of which is philosophy and its various branches. Understandings of the nature of information and of information-related phenomena are constructed in the light of developments in metaphysics, epistemology, ethics, and logic, as well as in the humanistic fields of art theory, literary theory, semiotics, linguistics, and history. Understandings of the activities of information users build on the behavioral and cognitive models developed in the life sciences: biology, psychology, cognitive science. Information systems design is informed by work done in engineering, technology, and design fields, including computer science; while information policy development and institutional management rely on insights generated by the social sciences and related applied fields: sociology, anthropology, political science, economics, public policy, business administration, and law. Notwithstanding one’s readiness to accept the particular formulation of the core of the information sciences presented above, the extent to which the content of the information sciences overlaps with that of “other” fields should be clear.

PHILOSOPHY

The question “What is philosophy?” is a meta-question about philosophy. It is one that arises in philosophy of philosophy (a.k.a. metaphilosophy). Answers of many different kinds have been proposed since the original identification of philosophy as a discrete field in the ancient era. These proposals may be categorized on the basis of the kinds of criteria on which each proposal distinguishes philosophy from other fields. For example, one proposal might be to distinguish philosophy from other fields by pointing to differences between the kinds of *phenomena* that form the subject matter of philosophy and those of other fields; another might point to differences in the kinds of *questions* that are asked in philosophy and in the other fields; another might point to differences in the kinds of *methods* that are used to answer the questions that arise in philosophy and in the other fields; while yet another might point to differences in the kinds of *goals* or purposes that motivate people to engage in philosophy and in the other fields.

Different kinds of proposals have attracted varying levels of consensus at different times and in different places. It is important, yet difficult, to avoid misleading

overgeneralization when characterizing the state of philosophy, even when the scope of the exercise is deliberately restricted to whatever is called “philosophy” by those who claim to practice it in a particular culture, such as the academy in the “western” world of the early twenty-first century. A simple caricature of the nature of philosophy at this point in its history might emphasize its concern with the most basic, fundamental, or foundational of phenomena (such as action, beauty, belief, being, causation, consciousness, evidence, existence, experience, goodness, identity, intentionality, justice, knowledge, meaning, necessity, rationality, reality, representation, responsibility, rightness, thought, time, truth, value, and virtue); its concern to ask the most basic of questions (such as “What is x ?” “How do we know that p ?” and “Why ought we do a ?”); its promotion of, and reliance upon, the most basic of methods in answering such questions (such as analysis of the very concepts that are used in expressing the questions, analysis of the logical form of arguments, and analysis of the mental processes by which we interpret our worlds); and its pursuit of the most basic of goals (such as truth, happiness, justice, peace, authenticity, power, and an understanding of the meaning of life). Such a caricature would fail to represent several significant respects in which metaphilosophy inspires ongoing debate:

1. The ways in which contemporary “western” philosophy is similar to and different from philosophy as practiced in “other” contemporary cultures, and from philosophy as practiced in earlier eras.
2. The ways in which philosophy as traditionally practiced is infected with systemic biases deriving from its domination by old, white, middle-class, heterosexual males.
3. The ways in which twentieth-century “analytic” philosophy (also known, somewhat misleadingly, as Anglophone or Anglo-American philosophy) is similar to and different from twentieth-century “continental” philosophy (also known, again somewhat misleadingly, as European philosophy).
4. The ways in which several historically specific “turns” or transdisciplinary shifts in emphasis (such as “the cognitive turn,” “the linguistic turn,” and “the cultural turn”) have affected different groups’ understanding of the nature of inquiry in general and the proper purpose of philosophy in particular.
5. The extent to which philosophy is conceived as having: 1) a normative or prescriptive rather than merely descriptive purpose, on account of which conclusions are drawn about how the world *ought* to be, as well as or instead of about how the world *is*; and 2) an “applied” as well as a “pure” function, in which real-world decision-making is informed by insights derived from philosophical analysis.
6. The ways in which different communities of philosophical practice emphasize different criteria for

evaluating the results of philosophical analysis: e.g., truth, correspondence with external reality, internal coherence, power, utility for producing testable theory, utility for controlling future events, richness of coverage, simplicity, and elegance.

7. The ways in which the methods and goals of philosophy are similar to and different from those of the empirical or natural sciences, and the ways in which, historically, the pendulum of dominant opinion has swung between rationalism (very roughly, the view that a priori knowledge is possible) and empiricism (which denies the possibility of any kind of justification for knowledge other than experience).
8. The ways in which philosophy may be divided into discrete branches or subfields.

At the most general level, it has become conventional to distinguish between, on the one hand, a small number of long-standing subfields such as metaphysics (which focuses on questions to do with being and existence), epistemology (knowledge and belief), ethics (goodness), aesthetics (beauty), phenomenology (experience), and philosophical logic (truth), and on the other, a much larger number of subfields with (in most cases) shorter histories, whose names typically take the form “philosophy of x .” There are branches of philosophy that are concerned with the fundamental ways in which human beings relate to their selves, to one another, and to their environments: philosophy of mind, philosophy of language, and philosophy of action. And there are branches of philosophy that are concerned with particular intellectual, creative, spiritual, social, and physical pursuits: philosophy of education, philosophy of art, philosophy of technology, philosophy of religion, political philosophy, and philosophy of sport. There are branches of philosophy that are concerned with particular disciplines, fields, professions, and practices: philosophy of science (including philosophy of physics, of mathematics, of psychology, of the social sciences, of the information sciences, etc.), philosophy of history, and philosophy of law. And there are branches of philosophy concerned with particular phenomena: philosophy of time, philosophy of race, and philosophy of information.

These branches of philosophy are themselves social constructs. Their boundaries are entirely arbitrary and far from definite. Insights derived from any one are regularly applied in (or, just as regularly, contradicted by) work done in another. Both philosophy of information and philosophy of the information sciences, for instance, are informed by many findings, claims, and proposals originating in other of the branches of philosophy listed above. That the findings, claims, and proposals that originate in philosophy of information and philosophy of the information sciences likewise inform the work done in those other branches is a claim that warrants further investigation (see “Conclusion,” below).

PHILOSOPHY OF INFORMATION

Some of the questions asked *in* the information sciences are philosophical questions and it is in this sense that philosophy and the information sciences overlap.

Metaphysics

Some of these philosophical questions are *metaphysical* questions, in that they are motivated by a desire to understand the essential nature of information-related phenomena, and the roles or positions of those phenomena within the totality of phenomena. For instance, we may ask: What is information? What are documents, data, records, meta-data? What are works, texts, editions, versions, copies? What are representations, reproductions, images? What are information sources, information structures? What is relevance, aboutness, authorship? What are subjects? What are authors, indexers, searchers? What is information production, reproduction, representation, preservation, storage, organization, access, seeking, transfer, retrieval, evaluation, use, destruction? The basic motivation for attending to questions of these kinds is the prediction that our answers—developed by carrying out careful analysis of the concepts or categories that we construct and use to think about real-world substances and properties—will help us to clarify our thoughts, strengthen our arguments, and improve the quality of the decisions and actions taken on the basis of the conclusions of those arguments.

Some of these metaphysical questions can be construed as *ontological* questions. Ontology is the branch of metaphysics that is concerned to identify and understand the fundamental categories or kinds of things that exist in the world. For any of the phenomena listed above, we may ask, What kind of thing is it? An abstract thing or a concrete thing? A universal or a particular? A substance or a property? An object or an event? A set or an element? One of the tasks of ontology is to identify and characterize these different categories.^[20] It may sometimes be helpful to distinguish between “pure” ontology in that sense and the “applied” ontology that is being done when information-related phenomena are being fitted into any predefined categorical structure.^[21] (Another sense of applied ontology is that which is used to encompass work on modeling the kinds of entities and relationships about which information is to be stored in databases.^[22]) In virtue of its focus on human-created artifacts that are the objects of human interpretation, ontology of information is closely related both to ontology of art (including ontology of literature) and to projects with metaphysical ramifications in philosophy of language and representation and in semiotics.^[23,24]

Epistemology

Some of the philosophical questions that are asked in the information sciences are *epistemological* questions, in that

they are motivated by a desire to understand the ways in which information and other information-related phenomena are involved in the processes by which belief can become knowledge.

In the information sciences, just as there is no standard conception of information, there is no standard conception of knowledge. The two main rival views are those of knowledge as true information (or information about the facts, i.e., information about the way the world really is), and knowledge as internalized information (i.e., the content of individuals’ mental images or representations of the world). These both differ from the theory of knowledge that is traditionally provided by epistemology, which is that knowledge is justified true belief. In other words, for any one of our beliefs to count as knowledge, it must be both 1) one that is true, and 2) one for which justification can be provided. Different forms of the traditional theory give different accounts of what it means for a belief to be evaluated as true, how the truth-value of a belief may be determined, how justifications of different kinds may be supplied, what degree of certainty is required of a justification, and so on.

For the information scientist, there is a dual motivation for studying and contributing to epistemology. In the first place, we may learn about potentially productive methods of generating information-scientific knowledge (see the section below on “Philosophy of the Information Sciences”). In the second place, if we accept the idea that there is some sort of conceptual relationship between information and knowledge, we are only a short step away from accepting that what we say about the nature of knowledge and about how it is acquired will influence what we say both about the nature of information and about how we collect, organize, and provide access to the content of information sources (i.e., recorded knowledge). An understanding of epistemology thus helps us to determine what our information structures, systems, services, policies, and institutions ought to be like, and what they ought to do, if the processes by which we interact with information are to result in the satisfaction of our “epistemic objectives”—e.g., the rapid, cheap, and easy acquisition of all and only those beliefs that are justified, true, and relevant.^[25]

Historically, there have been two main points of intersection between epistemology and the information sciences. Firstly, and as already mentioned above in the section on “Definitions of Information”, some accounts of justification rely on a particular conception of *information-as-evidence*. Secondly, library scientists were among the first to express and address the idea that the processes by which knowledge is acquired are significantly *social* in several respects. Margaret Egan and Jesse Shera were the first authors to use the term “social epistemology” in print, and focused on demonstrating how an understanding of the ways in which social groups (as well as individuals)

acquire knowledge can be applied in the design of information services to those groups.^[26–28] More recently, epistemologists such as Alvin Goldman have been concerned to give an account of the conditions under which social processes such as the provision and receipt of testimony can result in the acquisition of knowledge, and a number of philosophical analyses have been undertaken of trust, reputation, authority, reliability, and other criteria for evaluating the likelihood that information sources of various kinds will be productive of epistemically valuable beliefs.^[29–31]

Ethics

Several branches of philosophy deal with questions of value or goodness, and with claims about the kinds of things that ought to be done in given situations. Social and political philosophy, for example, are concerned with the evaluation of public policy, and governmental activity, and group interaction, and with the analysis of socially valuable states such as justice and freedom. Aesthetics is concerned to establish criteria upon which works of art may be evaluated. Ethics is concerned with the rightness of actions in general. Within ethics, some fairly fuzzy boundaries may be drawn between ethical theory, meta-ethics, and applied ethics. Ethical theories propose criteria for distinguishing between right and wrong actions; meta-ethics categorizes ethical theories and analyzes the concepts and assumptions on which they are based; and projects in applied ethics demonstrate the consequences of applying particular ethical theories as guides to action in particular situations.

As we approach the end of the first decade of the twenty-first century, information ethics is the most visible of subfields of philosophy of information. This is a field which already has its own international association, its own journals, and its own handbooks.^[32] “Information ethics” is typically understood to include “computer ethics,” and to emphasize questions about the ethical implementation and use of information technologies, but rarely to the exclusion of more general questions about the ethical provision and use of information services (online or off-line; computerized or not). For the information policymaker, systems developer, or service provider, the fundamental ethical question is: Who should have what level of access to what information? The issues that tend to arise in the evaluation of rival answers to this question include equity of access to information; intellectual freedom; information privacy and confidentiality; and intellectual property.^[33] The literature on each of these issues is large and straddles the boundaries between ethical theory, meta-ethics, and applied ethics. Further research on meta-ethical categories and concepts can only raise the profile of information ethics within mainstream philosophy circles even higher.

Other Branches

Other branches of philosophy upon which work in the information sciences has touched more than momentarily include philosophies of action, art, communication, education, history, language, law, logic, mathematics, mind, representation, science, and technology, as well as critical theory, hermeneutics, and phenomenology. A comprehensive review would require more space than allotted here. In an attempt to succinctly demonstrate the diversity of philosophical approaches that may potentially be taken in the information sciences, in this section a particular object of information-scientific study is selected, and a number of specific issues highlighted as ones that could be productively addressed from various, overlapping, philosophically informed perspectives. The selected object of study is the design of a service for the effective provision of access to relevant information resources or documents (i.e., a document retrieval or resource discovery system).

- What are documents? What kinds of things are they?—Metaphysics.
- What is the nature of the relationship between a document and the work that it instantiates? What is the nature of the relationships between a document and the classes of similar documents of which it is a member?—Philosophy of art; Philosophy of logic; Philosophy of mathematics.
- What do documents do? How do they “mean”? How do they inform?—Philosophy of representation; Philosophy of language; Philosophy of mind; Epistemology.
- How do documents serve as evidence? How does the informational value of a document relate to its evidential value?—Epistemology; Philosophy of science; Philosophy of history; Philosophy of law.
- What is the nature of people’s conscious experience of interacting with documents, with information, with information services?—Phenomenology; Hermeneutics; Philosophy of mind.
- What is information? What is the difference between information, education, and entertainment? What kinds of motivation do people have for choosing to engage with information, education, and entertainment services? How do we evaluate these interactions?—Metaphysics; Philosophy of action; Philosophy of education; Philosophy of communication; Philosophy of language; Philosophy of value.
- What is effectiveness? How do we determine how effective information services are?—Philosophy of value; Philosophy of technology; Epistemology.
- What is relevance? How does relevance relate to other epistemic values? How do we determine how relevant a document is?—Philosophy of logic; Philosophy of value; Philosophy of mind; Epistemology.

- What is access? How does access relate to other socially important objectives, such as preservation? In what ways are information services socially valuable? How should access to information resources be distributed among members of a given social group? How should resources be represented and organized so that access is optimized?—Social and political philosophy; Ethics; Critical theory.

PHILOSOPHY OF THE INFORMATION SCIENCES

Some of the questions asked *about* the information sciences are philosophical questions. The aggregate of these questions forms the field of *philosophy of the information sciences*. On a strict view, philosophy and the information sciences do not literally overlap in this sense, since philosophy of the information sciences is a branch only of philosophy (specifically, of philosophy of science), not of the information sciences.

The goals of philosophy of the information sciences may be stated as follows:

- To locate and illuminate the position of the information sciences as a group of fields in the universe of inquiry, i.e., to understand their role in interpreting and changing the world, their internal structure, and their relationships with other fields.
- To provide justifications for any decision to engage in information-scientific research.
- To provide orientations toward and directions for information-scientific practice by identifying the kinds of problems that are most significant, the kinds of questions that are most relevant, the kinds of methodologies that are most reliable, and the kinds of answers that are most acceptable.

There are two general approaches to philosophy of the information sciences. One is more descriptive, passive, and sociohistorical: the emphasis is on giving an explanatory account of what information scientists actually do, and what they have actually done, to locate themselves in the academic universe, justify their decisions, and orient their practices. Another flavor of philosophy of the information sciences is more prescriptive, active, normative, and (it might be argued) genuinely philosophical: the assumption is that philosophy of the information sciences should determine what the information sciences should be about, now and in the future.

Some of the questions asked in philosophy of the information sciences are *metaphysical* questions. For example: Do the information sciences share a distinctive ontology, or a distinctive view of the kinds of things that exist in the world? The short answer here appears to be “No.” Any acceptance, explicit or implicit, of a proposition that a given category of things exists is an ontological commitment.

Different theories in the information sciences, constructed by scholars working in different subfields, have different ontological commitments. Often, however, the precise nature of a theory’s ontological commitments will not be made clear at the time of the theory’s presentation, even though it may well be recognized that any evaluation of the theory will depend partly on an evaluation of those commitments.

Many of the philosophical questions that are asked about the information sciences are *epistemological* questions, in that they are motivated by a concern to understand the various kinds of knowledge that are produced, and the various processes by which knowledge is producible, in the information sciences. Even more specifically, such questions are normative, methodological questions about the ways in which research in the information sciences ought to be carried out—about the ways in which hypotheses should be tested, results interpreted, and theories constructed. Again, we might ask: Do the information sciences share a distinctive methodology, or a distinctive view of how knowledge claims might be generated and defended? And again the answer appears to be “No.”

One common way of distinguishing among fields of inquiry or communities of inquirers is to locate the fields or communities somewhere between two opposite poles according to their methodological assumptions. Kuhn,^[34] for instance, distinguishes between those academic communities whose members generally find themselves in agreement about the kinds of question that they ought to be asking (and about the kinds of method that they ought to be using to arrive at answers), and those “preparadigmatic” communities that presently lack such consensus (but that continue to strive toward it). Becher^[35] develops a two-dimensional model that distinguishes between the “hard pure” (natural sciences and mathematics), “hard applied” (science-based professions, such as engineering), “soft applied” (social professions, such as education and law), and “soft pure” (social sciences and humanities). In Becher’s model and others like it, the hard–soft dimension roughly corresponds to a scientific–humanistic distinction. “Hard” fields are restricted in scope, studying a clearly delineated range of physical phenomena with a limited range of tried-and-tested methods, with the positivist goal of establishing general, deterministic laws of cause and effect that can each be used to explain the occurrence of large numbers of discrete events. Members of “hard” communities tend to make objectivist assumptions about the nature of reality, of truth, and of knowledge: scientists typically proceed, for example, on the basis that it is possible to acquire knowledge of “the” truth about “the” real world. “Soft” fields, in contrast, are more open to the study of complex, messy, lumpy problems, using a wide range of exploratory methods to come to interpretative understandings, both of the unique constellations of factors that produce particular events, and of the meanings those events

have for individuals and for groups. Members of “soft” communities typically allow that our knowledge of the world (if not the world itself) is both socially constructed, in the sense that our beliefs are shaped not only by the ways in which we interpret others’ beliefs about the world, and perspectival or relative, in the sense that the “truth” (or goodness) of our beliefs may be evaluated differently depending on the evaluator’s present point of view.

Several communities of inquirers who have self-identified with a focus on information and information-related phenomena have a long tradition of soul-searching when it comes to locating themselves among the four quadrants of the Becherian model. Many commentators have drawn attention, in more or less exasperated tones, to the positivist nature of much of the research in the information sciences,^[36,37] and such observations have usually been accompanied by impassioned calls for a “softening” (in the Becherian sense) of information research. These days, we are more likely to read about information studies’ hospitality to a plurality of approaches, the implication being that each of its different subfields can be comfortably located in different quadrants, or even that each of its topics or problem sets can be explored using multiple methods originating in different quadrants. Bates,^[11] for instance, distinguishes nomothetic (hard, scientific, universal) from idiographic (soft, humanistic, particular) approaches, and describes 13 separate approaches to library and information science that can be located along the nomothetic–idiographic spectrum.

Humanistically oriented scholars are more likely to emphasize questions about the relations between information and the following (among other phenomena): conscious experience and the human condition; interpretation and sensemaking; meaning, language, and discourse; ideology, race, class, and gender; identity and diversity; preservation and cultural heritage; remembering and forgetting; narratives and stories; and aesthetic and moral value. Several attempts have been made to develop complete epistemological frameworks for such research, based variously on phenomenology, hermeneutics, critical theory, and discourse analysis. An understanding of philosophy of representation, itself a diffuse area, would appear to be a quality shared by proponents of the emergent view that the information sciences are properly about the relation between people and (not technology, nor even information, but) *reality*.^[38]

Comparative evaluation of the propriety of rival approaches to the information sciences is a difficult task. We could choose to ignore that the issue exists, or at least to deny that it is important (other than perhaps from a sociohistorical perspective), given that the bundling up of questions and methods to form more or less distinct fields is essentially arbitrary and varies historically and culturally according to how phenomena are perceived rather than according to how the phenomena change in themselves. A more productive approach might be to focus on establishing the criteria (truth, power, utility, etc.) upon

which different approaches may be evaluated, and the methods by which an approach’s “performance” against such criteria may be measured.

META-QUESTIONS ABOUT PHILOSOPHY

Just as there are meta-questions (philosophical, historical, sociological, and political) to be asked about the information sciences, there are meta-questions that may be asked both about Philosophy of Information and about philosophy of the information sciences. These include questions about when, where, and how philosophy of these kinds has been done, who it has been done by, and what motivations people have had for doing it. Such questions are asked by historians and sociologists of philosophy.

It is relatively easy to trace the histories of a few well-defined branches of philosophy of information: information ethics, information-theoretic epistemology, and social epistemology come to mind. But, taken as wholes, both philosophy of information and philosophy of the information sciences are diffuse, unbounded fields that lack scholarly associations, journals, textbooks, and reputations. The high-quality work that exists remains scattered, infrequently cited, and (one sometimes suspects) unread. The appearance in the early 2000s of several special issues of journals devoted to topics in philosophy of information demonstrates that the field is gradually attaining some degree of respectability within the information sciences (if not within philosophy); but, given the field’s lack of a clearly expressed identity, it is probably too early to expect any significant contributions to an understanding of its historical development. When that history is written, it will assuredly be of great interest to scholars wishing to see how the kinds of philosophical questions asked in the information sciences, and the kinds of answers offered, have changed over the years, which long-standing assumptions and beliefs (if any) have been challenged by the various paradigm shifts that have been identified in the broader academy, and how social factors have played a role in those developments.

Some of the meta-questions about philosophy of information and philosophy of the information sciences are themselves philosophical questions. For instance, we may ask what kinds of questions ought to form the content of each field, and how each kind of philosophy ought to be done. Contributions to the general field of metaphilosophy, which examine the nature of philosophy and the nature of motivations to engage in philosophical thinking, may serve as provocative resources in this regard.

CONCLUSION

The intent of this entry has been to examine the influence of philosophy on the information sciences. As part of any

general quest to understand the interdisciplinary nature of information studies,^[39] we may well wish to look in the opposite direction and ask, To what extent do the information sciences contribute to “mainstream” philosophy? The short answer here is... well, “Hardly at all.” The “trade deficit” produced by the imbalance between intellectual imports (from philosophy to information studies) and exports (to philosophy from information studies) could doubtless be demonstrated bibliometrically (see, e.g., Cronin and Meho^[40] for a description of the kinds of method that might be used). Certainly, the frequency with which contributions to the literature of the information sciences are cited in the literature of philosophy is vanishingly low. Moreover, the respective statuses within the general philosophical community of philosophy of information (in the broader, pre-Floridian sense) and philosophy of the information sciences sometimes seem to be roughly on a par with that of the philosophy of pasta. Things may change in the future as increasing numbers of philosophers first find inspiration in information-related phenomena and subsequently become aware of the existence of an entire field that, for one reason and another, has often struggled to attract the academic respect for which it has yearned. The most philosophically interesting of contributions to the information sciences—those with the highest potential value for philosophy, if only they were to be disseminated appropriately—include the following:

- Marcia Bates’s definitions of fundamental forms of information.^[2]
- David Blair’s analysis of the implications of contemporary philosophy of language for our understanding of information retrieval as a linguistic process.^[41,42]
- Brien Brothman’s deconstruction of conceptions of record and evidence in archival discourse.^[43]
- John Budd’s evaluation of the prospects for a phenomenological approach to information studies.^[44]
- Rafael Capurro’s assessment of the significance of intercultural information ethics.^[45]
- Ron Day’s critical-theoretic analysis of the discourse and rhetoric of the information society.^[46]
- Don Fallis’s development of epistemic value theory as an approach to the evaluation of information services.^[25]
- Luciano Floridi’s and Kay Mathiesen’s analyses of the moral value of information.^[47,48]
- Bernd Frohmann’s discourse-analytic reformulation of traditional epistemological frameworks for the study of scholars’ information behavior.^[49]
- Kenneth Einar Himma’s meta-analysis of justifications for the legal protection of intellectual property rights.^[50]
- Birger Hjørland’s examination of the epistemological assumptions underlying the practice of library and information science.^[51]

- Allen Renear’s examination of the metaphysical assumptions underlying the design of data models for library and museum catalogs.^[52]
- Keith van Rijsbergen’s (and colleagues’) demonstration of the utility of mathematical logic (including nonclassical systems of logic) for modeling the process of information retrieval.^[53]
- Patrick Wilson’s and Elaine Svenonius’s incomparable explications of the philosophical foundations of bibliographic description and organization.^[54,55]

BIBLIOGRAPHY

In philosophy, the standard encyclopedic sources are the 10-volume *Routledge Encyclopedia of Philosophy* (Craig, E., Ed; Routledge, 1998), and the continuously updated, online *Stanford Encyclopedia of Philosophy* (Zalta, E.N., Ed.; Metaphysics Research Lab, Center for the Study of Language and Information, Stanford University: Stanford, CA, 1997–). The standard bibliographic database is *The Philosopher's Index* (Philosopher's Information Center: Bowling Green, OH, 1967–). Leading publishers include Blackwell, Cambridge University Press, Oxford University Press, Routledge, and Springer. Useful series of collections of introductory essays to various branches of philosophy include the Blackwell Philosophy Guides, the Oxford Handbooks in Philosophy, and the Routledge Philosophy Companions. *The Blackwell Guide to the Philosophy of Computing and Information* (Floridi, L., Ed.; Blackwell: Oxford, 2003) is a title in the first of these series; Luciano Floridi's earlier monograph, *Philosophy and Computing* (Routledge: London, 1999) covers similar ground. *The Handbook of Information and Computer Ethics* (Himma, K.E., Tavani, H.T., Eds.; Wiley: Hoboken, NJ, 2008) is a comprehensive introduction to information ethics. The leading journals in philosophy include *Analysis*, *Journal of Philosophy*, *Mind*, *Noûs*, *Philosophical Quarterly*, *Philosophical Review*, and *Philosophical Studies*. There is no journal that is devoted exclusively to philosophy and information, but several titles cover areas of specialist interest: *Episteme* and *Social Epistemology* in epistemology; *Applied Ontology* and *Axiomathes* in ontology; *Ethics and Information Technology*, *International Review of Information Ethics*, *Journal of Information, Communication and Ethics in Society* and *Journal of Information Ethics* in ethics; etc.

In the information sciences, the standard encyclopedic source is, of course, the one you are reading. The cumulative volumes of the *Annual Review of Information Science and Technology* (ARIST; Information Today: Medford, NJ, 1966–) are equally indispensable. There are several bibliographic databases that cover different portions of the field: one with good international coverage is *Library and Information Science Abstracts* (LISA; ProQuest: San Diego, CA, 1969–). The environment for scholarly publishing in the information sciences is very diverse, and different subfields are represented well by different publishers (e.g., information retrieval by Cambridge University Press; digital libraries by MIT Press; museum studies by Routledge). There is no single text that provides a comprehensive overview of philosophical concerns in the information sciences, but monographs by Blair,^[42] Budd,^[56] Cornelius, Day,^[46] Frohmann,^[49] Hjørland,^[61] Svenonius,^[55] and Wilson^[54] serve as philosophically sophisticated introductions to their respective areas, as do chapters in ARIST by Blair,^[41] Capurro and Hjørland,^[57] Cornelius,^[59] Day,^[60] and Fallis^[25] (all listed in "References," above) Journals in the information sciences that carry philosophically informed articles on more than a very occasional basis include *Archival Science*, *Archivaria*, *Journal of the American Society for Information Science and Technology*, *Journal of Documentation*, *Library Quarterly*, and *Library Trends*. The Special Interest Group on the History and Foundations of Information Science (SIG/HFIS) of the American Society for Information Science and Technology (ASIS&T) regularly sponsors sessions of philosophical interest at annual meetings of ASIS&T, and the Conceptions of Library and Information Science (CoLIS) conference series is similarly receptive to philosophically themed papers.

Philosophy of Science [ELIS Classic]

Paul Evan Peters

University of Pittsburgh, Pittsburgh, Pennsylvania, U.S.A.

Abstract

The author notes: "...although a scientist may understand a science to the extent that he or she *does* science, a second level of understanding, that of understanding his or her understanding, may be absent." Philosophy of science is about that second level of understanding. That philosophy forms the basis of how and why a scientist conducts research, and conditions the judgments a scientist forms about the value and validity of the results of that research. Peters also addresses implications for library and information science.

—*ELIS Classic*, from 1977

INTRODUCTION

The philosophy of science is of fairly recent vintage as far as philosophical specializations go. Harré^[1] calls our attention to this fact by noting that the idea that the systematic sciences presuppose styles of inquiry different from those of the ordinary commerce of the mind did not really take root until the early nineteenth century. Before this time, what we have by way of a literature are the records of the methodological deliberations of scientists and the technical developments of epistemologists (philosophers of knowledge). It seems quite natural that at some point efforts would have been made to marry these two, in many ways different, literatures.

The courtship preceding the marriage began in the nineteenth century, but the wedding has not been an easy one to arrange. Representatives of the two families involved, that is, philosophy and science, have sometimes traded harsh words. It is not difficult to find scientists who resent the "intrusion" of philosophers who never have had to face the demands of empirical research. Philosophers can be found, moreover, who retort that scientists can be likened to clumsy bears wandering about in a woods with no concept of, or even a desire for a concept of, the geography of the forest. Ackermann^[2] illustrates this familial rivalry by calling attention to the awkwardness of the situation in which a philosopher is placed when queried by a scientist (particularly a physicist): Tell me something you've learned recently about science. The situation can be balanced by the philosopher reversing the initiative and questioning: Tell me something you've learned recently about philosophy. Socially, however, scientists seem to win the day, because, on the whole, it is philosophers who have declared an interest in science and not scientists in philosophy.

Such rebuffs and retorts may seem to be so much dirt in the laundry of the philosophy of science. In fact,

however, they are diagnostic of a most stubborn impasse in the foundation of a philosophy of science. This impasse, as phrased by Danto,^[3] is the attitudinal predisposition of philosophers and scientists alike that competent works in the philosophy of science are philosophic, for the former, or scientific, for the latter. It is the case, nevertheless, that since the nineteenth century, we can find not only individuals who are known for their philosophy but produced scientific works, such as René Descartes, or who are known for their science but produced philosophic works, such as Francis Bacon, but also individuals who refer to their works as the philosophy of science.

Some of these individuals, moreover, have produced "introductory" treatments and, consequently, have provided a resource from which we can derive a general appreciation for the scope of philosophies of science:

1. Hanson—exploration of the internal structure of scientific thinking.^[4]
2. Churchman and Ackoff—explication of the systemic presuppositions of inquiry.^[5]
3. Ackermann—explication of general, problem-independent principles of scientific practice.^[2]
4. Frank—systematic approach to the understanding of the tactics and strategies of science.^[6]
5. Harré—exposition of the principles operative in science that enable the acquisition of knowledge about the world and the things in it.^[1]
6. Lambert and Brittan—analysis of conceptual and methodological issues in science and exploration of how science, as an experience, relates to human activity in general.^[7]

An attempt to synthesize these six statements (among others) concerning the scope of philosophies of science results in a statement to the effect that a philosophy of

science constitutes a critical understanding of science. The word “critical” in this statement is important in that it implies that the ways in which science is understood are themselves subjects for examination and understanding. Consequently, although a scientist may understand a science to the extent that he or she *does* science, a second level of understanding, that of understanding his or her understanding, may be absent. The degree to which this second level (and an infinite number of other levels defined similarly) is missing in the thinking of science (or a science) is the degree to which science’s (or that science’s philosophy) is undeveloped.

In discussing the critical understanding of science attempted by the philosophy of science, it is important for us to keep in mind that its understanding is just one such of a number possible. Others have come, recently, to be subsumed under the umbrella descriptor of “sciences of science.” The closest of these to the philosophy of science is probably that of the history of science. Whereas, however, history of science inquiries usually result in descriptive expositions (as is characteristic of history), those of the philosophy of science result in prescriptive developments (as is characteristic of philosophy). These sciences of science will occupy our attention again in the final section of this article.

ORGANIZATION

Our objectives for this article are two: *a*) we want to conduct a survey of some of the thinking that has been done in the name of the philosophy of science and *b*) we want to open discussion of how this thinking can be said to apply to the work of library and information scientists. The “applications” aspect of this article is included more for crystallizing the material around familiar seeds than for any other reason. It is hoped that each reader will be able to think through her or his own applications, given the material of the survey.

It is evident that a survey can take any of a number of forms. Some surveys are organized around people, others around eras, and still others around issues. The organization of the present survey is that of “-isms.” Other authors who have employed this style are Churchman and Ackoff,^[5] Churchman,^[8] Pepper,^[9] and Turner.^[10] (What we understand by “-ism,” others have called “school.”) It is possible to overwork the notion of an “-ism.” Consequently, before we identify those we will cover, we do well to take steps to clarify our intentions. (Our development in this area is related to Ackermann’s discussion of scientific theories.)

When discussing the genetic constitution of an organism, it is convenient to make a distinction between “genotypical” and “phenotypical” characteristics. Genotypical characteristics are those said to be encoded in the organism’s genetic makeup, while phenotypical characteristics are the result

of the interaction between this makeup and a specific environment. Insofar as an organism is always in an environment, we can observe only phenotypical characteristics and, by examination of a number of “similar” organisms, infer genotypical characteristics. Since genotypical characteristics are inferred, they stand as idealizations and, as a result, no one expects to be able to observe them directly.

As we discuss the characteristics of philosophy of science “-isms,” we will be dealing with the genotypical. This is to say that when we outline an “-ism” in terms of the way in which an “-ist” views the world, the “-ist” does not actually exist. Nevertheless, we will name historical personages and label them as an “-ist” of one type or another. It should be understood from here forward, however, that when we do this, we mean to say that the person involved is more of this type of “-ist” (has more of the characteristics of this “-ism”) than he or she is of any other.

With these cautionary comments in mind, we can turn to identifying the “-isms” of our survey. This identification has been accomplished by grouping orientations assumed by philosophers of science as they have considered the following two questions:

How should scientists conduct their inquiry?

What should be our attitude toward the products of scientific inquiry?

These questions are not the only ones asked by philosophers of science. Nevertheless, they can be said to account for much of that which philosophers of science have debated among themselves. We shall refer to the first of these questions as the “how” question and the second as the “what” question.

Given these two questions of interest, we note that it is possible to find philosophers of science who agree in their orientations toward one and disagree on the other. Consequently, we have at our disposal a two-dimensional classification of philosophy of science thought. This classification is represented by the matrix shown in Fig. 1. Therein the “-isms” associated with orientations toward the how questions are displayed as rows, while those associated with orientations toward the what question are given as columns. Some “-isms,” moreover, are presented in parentheses. These are “-isms” that we will develop as “modern” variants of traditional approaches.

The matrix in Fig. 1 expresses exactly the way in which we will organize our survey. Our first concern will be that of orientations toward the how question. This discussion will be followed by one centering around orientations toward the what question. As mentioned at the start of this section, the material of these survey sections will be focused through a perusal of what the philosophy of science might be said to have to do with the work of library and information scientists. After that, the article will

How question	What question	
	Conventionalism	Realism
Rationalism (speculativism)		
Empiricism (positivism)		
Criticism (pragmatism)		

Fig. 1 Two-dimensional classification of philosophy of science thought.

conclude with an articulation of some of the present and future issues in the philosophy of science.

ORIENTATIONS TOWARD THE HOW QUESTION

All vital questions raised by philosophers seem to attract a great deal of attention directed at stating them precisely and clearly. Authors can be observed to begin discussions so directed with the query: What is it that we are really asking? Answers to such second-order questions usually lead directly to answers for the original question.

The two questions that we have chosen are philosophically vital in the above sense. For this reason, we can say that it is according to the way in which an author formulates the how or the what question that we will class him or her as an “-ist” of one type or another. Authors can be said to subscribe to the same “-ism” by virtue of the similarity of their statement of questions.

Applying this reasoning to the how question leads to three main “-isms”: rationalism, empiricism, and criticism. Each of these had reached a high degree of sophistication prior to the nineteenth century. Consequently, each has had an opportunity to undergo growth sufficient to allow identification of “modern” variants. These contemporary counterparts are known as speculativism, positivism, and pragmatism, respectively.

In this section, our primary concerns will be those of the traditional “-isms.” This is the case for two reasons: *a*) due to their place in history, the traditional “-isms” appear more “stable” than their modern versions and *b*) we have provided for a section dealing with “current and future issues” in this article and can focus upon the modern there

rather than here. Consequently, our immediate plan is one of laying out the traditional and discussing the modern only insofar as they can be said to carry on certain lines of thought.

We can convey a quick notion of who the people involved were, how they formulated the question under discussion, and what answers they provided. Some of the principal proponents of each “-ism” were:

Rationalism—Leibniz (1646–1716),^[11] Descartes (1596–1650),^[12] and Spinoza (1632–1677)^[13]
Empiricism—Locke (1632–1704),^[14] Berkeley (1685–1753),^[15] and Hume (1711–1776)^[16]
Criticism—Kant (1724–1804)^[17,18]

These people can be said to have formulated our how question as follows:

Rationalism—What are the simplest ideas which: *a*) can be had by a scientist and *b*) are sufficiently “powerful” as to make their correctness unquestionable?
Empiricism—What are the simplest sensations which: *a*) can be had by the scientist and *b*) are sufficiently “clear” as to make their existence unquestionable?
Criticism—What capabilities must a scientist have prior to an inquiry in order to make judgments about the experience represented by that inquiry?

These formulations, in turn, lead to the following answers:

Rationalism—Scientists should conduct their inquiry so that it is guided by theory.

Empiricism—Scientists should conduct their inquiry so that it is guided by data.

Criticism—Scientists should conduct their inquiry so that it is guided by both theory and data.

Rationalism and empiricism were, and are, diametrically opposed positions that became synthesized with the advent of criticism. Such a synthesis was required because both rationalism and empiricism, taken separately or together, were, in one degree or another, inadequate for the explanation of certain notions judged basic to science. The explication of the areas of adequacy and inadequacy of both rationalism and empiricism will be our first concern.

For both rationalists and empiricists, the component of science requiring the most explanation is the ability of its practitioners to make any “sense” out of the flows of perceptions that arise from interactions between the human sensorium and the energies of the universe. Characteristically, a rationalist looks to the world of sensory experience and finds no permanence, no order, no intelligence; in short, he or she finds a world of appearance. Rationalistic reasoning led to the conclusion that the fact that there is any stability in human perception is due to the existence of certain simple concepts. These concepts were said to be used by the scientific *mind* to recognize the things contained in the chaos of sensation. Scientists come to make sense of the world, rationalists proposed, when they come to see instances of concepts.

Let us illustrate the rationalist program to the extent that we have presented it. In the world of everyday experience there are familiar objects that we call “chairs.” None of us would claim that we have seen or will see all chairs. We know that chairs are manufactured according to different designs and are fabricated from different materials. Yet none of us feel particularly stressed when applying the term “chair” to an object we have never seen, manufactured by a design we have never seen, and fabricated from materials we have never seen. Rationalists concluded that this state of affairs is possible only because there exists a concept of “chair” that is common to all human reasoning and that can be employed by each of us to recognize, without hesitation, that each of a number of sensually dissimilar things is, in fact, an instance of this concept.

Rationalism received its justification from the “force” of the double-edged proposition that God exists and is good. From this basis, rationalists proceeded to conclude that a good God would not construct an unintelligible universe. Consequently, as we have said in the above, it was asserted that the flux of reality was deceptive. The problems of science were proposed to be: *a)* the discovery of the simplest of ideas and *b)* the combination of these ideas to develop other ideas. The methods appropriate to science were claimed to be intuition, for discovery, and deduction, for combination. The correctness of the products of intuition was debated according to the “principle of contradiction,” which required that for an idea to be

judged correct, it must be impossible for the universe to be otherwise. The products of deduction, moreover, had their correctness assessed according to the demands of logic wherein the principle of contradiction also played a role in that a combination of ideas would be judged to be incorrect if it could be shown that it asserted the opposite of other ideas that were already accepted as correct.

The twentieth-century mind, in general, has not been sympathetic to the rationalist program. It somehow seems incredible that philosophers and scientists would have proposed that intuition was the primary method of discovery appropriate to science. Although we will soon have much more to say on this, it seems important to itemize, at this point, some of the contributions to science made by scientists who ascribed to rationalism. First of all, Leibniz was a rationalist, and he, with Newton, added integral calculus to the armamentum of science. Descartes, to whom we owe gratitude for the Cartesian coordinate system, was also a rationalist. Finally, almost all of mathematics, in particular, and logic, in general, can be said to be motivated by rationalistic considerations.

It is much, therefore, that science can be said to have gained as a result of the efforts of individuals who believed deeply in a rationalistic philosophy. The fact remains, however, that the rationalist program was, in a sense, lopsided. Rationalism could always talk with more confidence and precision about deduction than it could intuition. The question of discovery of simple ideas and the associated validity of the entire rationalistic program loomed large. This was particularly the case because empiricism submitted that the notion of “simple ideas” was confused altogether.

It is difficult to imagine how two systems of belief could be more fundamentally opposed than those of rationalism and empiricism. Whereas, as we have discussed, rationalists viewed the products of sensation as intelligible only when based in thought, empiricists viewed the products of thought as intelligible only when based in sensation. Empiricists located the responsibility for the flux and chaos of experience in the mind. The world as we see it, the empiricists submitted, is simple and clear. It is the influence of undisciplined operations of the mind that introduces confusion. Whereas the existence and goodness of God is a matter of mere opinion, the clear and distinct sense impressions of a crisp, juicy, sweet, and red apple are undeniable facts. It was the proposition of the empiricists that scientists come to make sense of the world when they begin to notice the similarity of certain simple sensations among a number of objects.

Empiricists have always been quick to call attention to the superfluity of rationalistic beliefs when compared to theirs. As an example of this, consider the experience of pain. For an empiricist, pain is understood to be simply and distinctly forceful in its influence of the mind of man. There is no need to assume, with the rationalists, that a concept of pain is needed for the experience of pain. As

children, each painful experience we encounter is unique. With time, we come to associate the similarity of all painful experiences and to develop a general notion of pain together with a system of types (such as dull, sharp, shooting, and the like). It is the sensation of pain that enables the recognition of a concept of pain. If it were otherwise, then children would have to be assumed to partake of the same experience as adults. For an empiricist, this implication of rationalism was decidedly absurd.

The justification of the empiricistic attitude was one of common sense (almost taken literally). Empiricists challenged scientists to admit that colors and shapes of things are trustworthy, while their naming of things was error prone. From this framework, the problems of science that empiricists recommended were observation and induction. The products of observation, that is, the simplest sensations, were verified by the agreement (consensus) of scientists performing the observation (either together or separately over time). The ideas admitted by induction, moreover, were said to be judged according to the “sufficiency of evidence” invoked in the induction.

Previously, we commented that the twentieth-century mind has not been, in general, sympathetic to rationalistic science. This is, in part, demonstrated by the fact that for most of us, our basic image of science is one of controlled observation of the world through experimentation, an image of empiricistic origin. All “good” scientific investigations must be replicable. All “good” scientific theories must fit the “facts.” It is easy to recognize the empiricistic program as it enters our daily lives through social values and customs. Logical thinking is also a scientific value, and we still turn to rationalists to give us assistance in this area. Yet we refer to them as “logicians” instead of “scientists.”

Rationalism was challenged by empiricists to explicate the origins of simple ideas. Such an explication, the argument was made, was the whole point of science. The program of empiricism proposed an explication, as we have discussed, involving a notion of simple sensations and induction in contrast to the simple ideas and deduction of rationalism. It is important to note, however, that the observations of simple sensations are “guaranteed,” so to speak, by the trustworthiness of consensual agreement. The execution of induction, furthermore, is guaranteed by a belief in the principle of sufficiency of evidence. Rationalists challenged empiricists to explicate exactly how the principle of sufficiency of evidence could *itself* be verified. Using this approach, rationalists argued that empiricism was at fault due to circularity of reasoning.

As might be expected, adherents to rationalistic and empiricistic orientations toward our how question did not find much ground for thoughtful communication. There was one rationalist, however, who, late in his life, heeded the arguments of an empiricist and proceeded to define a new orientation. The rationalist was Immanuel Kant. The

empiricist was David Hume. The emergent philosophy of science “-ism” was criticism.

The message that Hume^[16] sent from England to Germany (which, incidentally, was the direction of most empiricistic critiques of rationalism) was contained in a revolutionary account of the scientific use of the notion of “causality.” Hume had believed in the empiricistic proposition that we come to awareness of the cause of something, say B, by observing that it is always preceded by another thing, say A. It is said that while playing billiards one evening, Hume, by observing the interaction of the balls on the table, recognized that all one could correctly say is that “B succeeds A.” He concluded that the notion of causality made no sense or was, at least, superfluous when viewed strictly from an empiricistic vantage point. The situation was no better, he discovered, in the rationalistic camp. In order for a rationalist to state that “A causes B” it would have to be assumed that the concepts of A and B “provided” for their causal relationship. Otherwise, the concept of A causing B could not be deduced from their individual concepts. But this would require our concepts of everything to include provisions for their relationship to everything else. This, Hume concluded, would result in our concepts being “unworkably” broad. Hume thus argued that the notion of causality was not scientific and that it should be abandoned.

Kant^[17] accepted Hume’s devastating thesis, announced that the notion of causality had to be “saved,” and set about the task. Evidently, the only way that this salvation could have been accomplished was by formulating a new orientation. This is what Kant attempted and his approach was one of synthesis of rationalism and empiricism. As mentioned in the above, the synthesis he devised came to be known as “criticism.”

The fundamental premise of the criticistic orientation was that the products of scientific inquiry originate neither *exclusively* in the world nor the mind. Rather, these products are the result of a process of cooperation between thinking and sensing. For a criticist, simple sensations or simple ideas simply do not exist. Instead, there are actions of judgment that are made possible when the mind structures reality as presented through the senses. A criticist would regard our how question as directed to the problem of a scientist deciding exactly how to conduct her or his observation. When asked how a scientist should conduct inquiry, criticists think of the structure of the world that must be assumed in order for observation to be possible.

The criticistic program called for the senses to provide the contents of our scientific judgments while the mind provided their form. As examples of what criticists meant by “form,” we cite space, time, and a number of “categories of the understanding.” One of these categories Kant defined “as to Relation” and it included, among substance and community, cause. Herein Kant’s proposed solution of the Humean problem can be found. Whereas the senses

inform us as to what needs to be related, the mind performs the relation. One such category of performance results in the judgment that A causes B. We find causality neither in the world nor in our concepts, suggested Kant, not because there is no causality but because it is contained in the *operation* of the mind.

Over time, the details of Kant's philosophy have been shown to be in error by developments in science itself. For instance, Kant accepted the Newtonian treatments of space and time as basic to the operation of the mind. Einstein and his followers have taught us that it is logically possible to think otherwise and that it is empirically mandated in certain situations to do so. Nevertheless, the criticistic orientation toward our how question deserves a place alongside of its parents, rationalism and empiricism. Rationalistically oriented scientists have given us logic, empiricistically oriented scientists have given us experimentation, and criticistically oriented scientists have given us motivation to temper our logics with experiments and our experiments with logics.

With the articulation of criticism, the divisions between orientations toward our how question have become progressively less distinguishable. It would be admitted now by almost all scientists and philosophers of science that scientific theories do not occur in the minds of people without some provocation, brought to bear by data from experimentation, as to what it is that needs to be theorized. Observation in the name of science, moreover, is generally accepted to require some theoretical deliberation if only to define the extremes that can be measured by the instruments to be used. The issues of debate among interested parties in the twentieth century seem to have become those of "degree" (the degree to which intuition is important and the degree to which observation is important), with speculation emphasizing intuition and positivism, observation.

As we have mentioned in one way or another a number of times in this section, it is speculation, the modern version of rationalism, that is on the defensive in contemporary discourse. The speculative program claims that certain sciences, particularly those dealing with life and society, are intrinsically intuitionally based. This is to say that important components of the conceptual frameworks associated with these sciences will never be able to be expressed in terms that enable observation. Consequently, speculatists reason, there will always be a central place in science for intuition. Realizing this, a number of speculatists, Husserl,^[19] for example, have devoted attention to the development of well-circumscribed intuition methods.

Positivists, on the other hand, have responded to speculativistic arguments by acknowledging that unobservable concepts may be required by science, but the extent to which they are required is the extent to which the body of knowledge involved is prescientific. The demand of positivists is that scientific knowledge be "positive" in the sense

that it make assertions about things that are observable. The meaning of *scientific* terms, argue the positivists, is nothing more and nothing less than the operations required to observe the terms' referents. Terms for which such operations cannot be specified are said to be nonscientific. The fact that there are other types of meanings than those scientific should not influence the scientist. As well, positivists regard the analysis of the language(s) of science as one of the most important tasks to be performed by philosophers of science.

Two individuals who have done the most with the positivistic orientation as we have discussed it are Carnap^[20,21] and Bridgman.^[22] Other individuals involved in the speculation-positivism debates are:

Speculation—Whitehead (1861–1948)^[23] and Bergson (1859–1941)^[24]

Positivism—Mach (1838–1916),^[25] Wittgenstein (1889–1951),^[26] and Ayer (1910–)^[27]

It seems important to note that the positions of both speculation and positivism can be said to be reasonable. Scientific knowledge, as we have come to understand it, must be based on publicly available information. Positivists have concluded that this requires that scientific knowledge be based on observation even though at some point some of the components of that knowledge may have been little more than very private, and very tentative, intuitions of some scientists. Speculatists complain that the labeling of the products of intuition as nonscientific or prescientific is an arbitrary and dangerous limitation of the scope of science. To them, it seems warranted that whatever influences, the development of scientific knowledge be considered to be part of science.

Speculation and positivism can be said to have arrived at the same sort of communication impasse as their forebears, rationalism and empiricism. Criticism, we have seen, attempted to break this barrier by demonstrating how the scientific mind could be both rationalistic and empiricistic at the same time. Although criticistic arguments seem to have succeeded in this demonstration, the resurgence of rationalism and empiricism can be interpreted as an indication that the criticistic thrust did not cut deep enough. Pragmatism can be viewed as the modern version of criticism in that it attempts to demonstrate how a philosophy of science can harmonize speculation and positivism.

The basic component of the pragmatic orientation as we shall discuss it is that a *science* can be both speculativistic and positivistic at the same time. Pragmatists bring to the surface of contemporary debates the fact that at any given time a science involves a number of different individuals at different stages of understanding of different (types of) problems (phenomena). Some of these individuals may be speculativistic in their outlooks, while others may be positivistic. Pragmatists regard as unnecessary the classification

of concepts as nonscientific simply because they are speculativistically based. The classification of fields of inquiry as nonscientific simply because their practitioners are predominantly speculativistic is similarly viewed.

For pragmatists, science as an activity is not as separable from other forms of human activity as other philosophers of science seem to view it. The relations among sciences, that is, physics, biology, etc., moreover, are not as cut-and-dried as many would have it. The question of what psychology has to say to physics, or what art has to say to physics for that matter, is meaningless to a pragmatist unless a problem has been defined. Once a problem has been specified, the importance of a solution to the problem assessed, and an inventory of available knowledge accomplished, a pragmatist will accept anything as scientific that contributes to the attainment of a state of knowledge that is appropriate to the importance of the problem.

Pragmatism, then, attempts its synthesis of speculation, positivism, and the other orientations we have covered in this section by focusing upon the inquiry of science rather than of individual scientists. Some of the people who have enunciated a pragmatic philosophy of science are James (1842–1910),^[28] Dewey (1859–1952),^[29] and Singer (1873–1954).^[30] It should be noted, as we complete this discussion of pragmatism, that pragmatic thinking has not received the same recognition from speculation and positivism as did criticism from rationalism and empiricism. Some additional remarks will be made on this point when we turn to the current and future issues in a later section.

It has been our goal in this section to expose some of the main currents in the thoughts that philosophers of science have given to the question of how scientists should conduct inquiry. This we have done by discussing the tenets of orientations to the question that we obtained by grouping the efforts of individuals who can be said to have formulated the question similarly. Although this survey has focused on the “-isms” so defined, it is important to recognize the issues involved to be basically those of the relative contributions to be made to science by intuition versus observation and deduction versus induction.

ORIENTATION TOWARD THE WHAT QUESTION

The second question that we selected for the survey of this and the preceding section was: What should be our attitude toward the products of scientific inquiry? In comparison to our first question, the meaning of this second query is less obvious. Its history, moreover, is considerably less extensive in that it has only been an active area for debate since the middle of the nineteenth century. Nevertheless, deliberations in its name have become increasingly commonplace in recent times.

Before proceeding much further, we had best be clear about our understanding of the question. First of all, we acknowledge that the products of scientific inquiry are manyfold. The specific class of products that we are addressing with the question, however, is that of “theories.” Generally, we want to avoid the question of what the structure of a theory might be said to be [see Campbell^[31] or Braithwaite^[32] for expositions of widely accepted views]. The question that we do want to raise is that of the *function* of scientific theories. The debate that we want to survey has been concerned with the correctness of supposing that we can do certain things with theories.

To illustrate the form of this debate, we appeal, for the moment, to what is probably the most prevalent opinion on the subject. For many of us, scientific knowledge in the form of theories constitutes the “safest” and most “useful” knowledge that we humans can achieve. It is “safe” in the sense that it is dependably error-free. It is “useful” in the sense that it is tailored to provide solutions to problems of survival. No matter how strongly we might argue that the cost of scientific knowledge is excessive or that the methods by which it is obtained are inhumane, scientific theories have the advantage that they “work.” They have provided direction for handsome material development, they have enabled us to reach for the stars, and they have justified utopian visions of disease-free societies. In sum, scientific theories enable us to predict, explain, and control the events of our world with precision.

The view of scientific knowledge that we have just articulated can be analyzed to expose an orientation toward our what question. For instance, we note that the viewpoint assumes: a) that a world of physical objects and processes exists independent of the scientific mind; b) that the nature of these objects and processes are (in principle) knowable; and c) that scientific theories are the most precise form of such knowledge attainable. Debates on the merits of the third part of this characterization usually occur between scientists and nonscientists, and even though they are fascinating, we have omitted any record of them from this article. There has been debate in philosophers’ circles, moreover, on the appropriateness of the assumption that a world exists independent of the mind, but we will also leave that discussion to another place and another time. What we will take up for discussion are the thoughts of those scientists and philosophers of science who have found themselves more in agreement than not when comparing attitudes toward questions about the existence of a physical world and the precision of scientific knowledge relative to other forms of human knowledge but, all the same, disagree radically on the issue of the knowability of the physical world.

The orientation that holds that scientific knowledge does constitute an understanding of the nature of things in the physical world has come to be called realism. Two of

the individuals who have thought through realistic positions are Moore^[33] and Ryle.^[34,35] Most of the rationalists and empiricists whom we cited in the previous section can be said to have been realists to one degree or another. In addition, a number of psychologists have attempted to develop theories of sense perception that are overtly realistic ["Gestalt" theorists, such as Köhler,^[36] for instance, postulate that the contents of reality and those of the mind are "isomorphic," i.e., are in a one-to-one correspondence]. Turner^[37] can be cited as a contemporary, philosophically minded psychologist who openly discusses his commitment to realism.

Realists are opposed by a number of points of view that agree to the extent that they all emphasize the strongly *conventional* rather than *real* character of scientific knowledge. Individuals of this orientation frequently refer to certain events in the history of science in order to convey an appreciation for why they have brought the realistic thesis under examination. Inventories of these events always include the "revolutions" of Copernicus and Einstein whereby complete systems of scientific knowledge, those of Ptolemy and Newton, respectively, were summarily replaced.^[38–40] Mention is also made of developments in modern physics (in the form of quantum mechanics) that have led to the conclusion that there are limits to the ability of the human mind to know in real terms.^[41] Even the world of mathematics, the contents of which lie beyond the perceptive powers of most of us, has been the scene of similar developments.^[42–44] It is noted, moreover, that astrologers and alchemists once laid an unchallenged claim to being scientists; and ether, phlogiston, and humors once laid a similar claim to being scientific, realistic concepts. In no small way, the history of science can be said to be littered with the decaying parts of discarded theories and concepts.

It is not the case that realists ignore the dramatic events itemized in the previous paragraph. Rather, they don't accept the conclusions that "conventionalists," as we will call them, can be said to draw from the study of the history of science. Realists claim that it is to be expected that science's movement toward *real* theories should exhibit progress whereby concepts and theories are refined. Events such as the replacement of Ptolemy by Copernicus and Newton by Einstein should be viewed as nothing more than "growing pains." The assertion that scientific theories are realistic *in principle* cannot be rejected simply because we haven't yet achieved perfect science.

Conventionalistic response to realistic arguments can be said to have appeared in two major forms. First of all, there are those who have held that science doesn't need to assume a realistic attitude. This tactic has been most forcefully adopted by psychologists of a behavioristic bent^[45,46] and has come to be known popularly as the "stimulus-response," "black-box," or "input-output" view of things. It has also influenced philosophic treatments of

cybernetics [that of Craik,^[47] for example]. Essentially, this strain of conventionalism, which has also been called "instrumentalism," holds that science need only record the correlations of actions performed by scientists and results observed. Introduction of any additional material into scientific theories is said to be unnecessary.

A second conventionalistically motivated response to realism can be found in the writings of Mach,^[25] Poincaré,^[48] and Duhem.^[49] The suggestion of these authors, among others, is that the realistic attitude is inappropriate. It is their assertion that the reality of a theory cannot be assessed on *scientific* grounds. How could such an assessment be performed, they ask, without a comparison of the contents of the theory with those of reality itself. Obviously, such a comparison is impossible because it presupposes knowledge of that which is unknown. These conventionalists acknowledge that one theory can be said to be unrealistic in comparison to another in the sense that it does not account for observations as adequately. But, they are quick to remind us, science has experienced in its history the "unfortunate" co-occurrence of theories that account for the same observations to the same degree of accuracy. To say that one such theory became ascendant because it was more *real*, they conclude, is to postulate an impossible decision-making capability.

In the place of a realistic orientation, conventionalists of the form we are discussing would substitute an orientation that views scientific theories as "languages" by which scientists can communicate results of observation unambiguously and economically. It is not to be denied that the contents of these languages are provoked by reality as observed, but it is to be contested that they tell us about that reality as it is unobserved. If Duhem's program is followed,^[49] it is held that the relationships among the contents of a theory, on the one hand, and the relationships among the contents of reality, on the other, move toward a coherence over time, but beyond this "natural classification," little more of the realistic attitude toward scientific theories can be interjected.

The survey of conventionalistic critiques of realism that we've conducted to this point hopefully engenders an appreciation for why the assumption of "in-principle knowability of reality" has come under examination. Without introducing considerable additional detail, it would be difficult to take the discussion much further. It has been our intention in going this far to demonstrate how quickly the deceptively simple question "What should be our attitude toward the products of scientific inquiry?" becomes complicated when investigated critically. As with the previous section, it is important to keep in mind the issues that have structured debate about the question. For our what question, these issues can be said to be those of the (in)appropriateness, (un)necessity, and (im)possibility of the attitude toward scientific theories as constituting real versus conventional knowledge of the world.

APPLICATION TO LIBRARY AND INFORMATION SCIENCES

At the start of this article, the promise was made that our survey of philosophy of science thinking would be applied to the problems of the library and information sciences. To produce such an application in the full form possible would be to develop a philosophy of library and information sciences. This we cannot do within the scope of a single article, but we hope to sketch out the components and promise of such a philosophy.

If we recall, for a moment, the definition of “philosophy of science” that we introduced for our discussion, we will be able to develop precisely what function a philosophy of library and information science might have. This definition stated that a philosophy of science constitutes a critical understanding of science where the word “critical” implies that the means by which the science is understood are themselves subjects for examination and understanding. People who dedicate thought to the philosophy of science, or to the philosophy of a science, therefore function, through the results of their work, to enable scientists to be more selective, more conscious about what they do and the ways they do it than they might be otherwise. This is the case, that is, if there exist open lines of communication between the two groups of scholars (those concentrating on the science, on the one hand, and those concentrating on the philosophy, on the other).

Stated in familiar terms, those who work upon a philosophy of a science assist those who work in that science in conceptualizing design options and interpreting situations. The options available to an individual approaching a system or an experimental design task can be categorized, given sufficient work, along the lines we followed in discussing our how question in previous sections. This is to say that a design task essentially raises questions about how something should be done and, philosophers of science assert, answers to such questions, upon examination, can be said to contain rationalistic, empiricistic, and criticistic orientations. It follows that a scientist who is able to recognize and analyze the strengths and weaknesses of these orientations is better equipped to formulate and evaluate design alternatives than one who is not.

Library and information scientists, for instance, face daily the problem of representing the contents of documents. Whether the mode of representation is that of classifying, abstracting, or indexing, to cite three, the problem remains to be one of developing a “substitute (surrogate)” for a document that enables that document to be related to other documents for purposes of storage and retrieval. We solve this problem by using classification and indexing systems. The designs of these systems have evolved over time and can be viewed to demonstrate the philosophy of science orientations we have discussed. The approach to classification adopted by Dewey, for example, relied heavily upon a conceptualization of the universe of

knowledge, while that of the Library of Congress is based more upon the actual contents of documents themselves. In this respect, the Dewey decimal classification, oriented toward the ideational, can be said to be predominantly rationalistic while the Library of Congress classification can be said to be predominantly empiricistic because it is oriented toward the observable. S.R. Ranganathan, moreover, with his colon classification, can be recognized to have assumed a criticistic orientation. This is by virtue of his use of the process-matter-energy-space-time formula in the context that *every* document contains something about each of these facets (an ideational assertion), but what is contained has to be determined by continual surveillance of published literature (an observational assertion).

The point of discussing how library and information scientists have gone about designing systems for representing the contents of documents, however, is not to claim that the designers involved used philosophy of science thought to guide their work. Rather, this brief exposition stands as evidence for the proposition that philosophers of science do serve to help the practicing scientist understand more fully the ways things have been done in the past and the ways they could be done in the future. Faced with a problem of design and equipped with a comprehension of philosophy of science, scientists could explore, at the outset of work on the problem, the rationalistic, empiricistic, and criticistic viewpoints to the problem. Such an exploration would result in a preliminary inventory of subproblems, subtasks, associated with the theory that has to be invoked relevant to the problem (rationalistic), the data that has to be collected relevant to the problem (empiricistic), and the means by which the theory and the data can be matched to evaluate the effectiveness of the design (criticistic). This inventory, in turn, can function to clarify what the design could do and, after consideration of the practical, what it can do. It is in this latter category, that of what is practical for a design, that the inventory is again very useful because it enables an understanding of what the design is not doing. Thus, the task of explaining design failures, after a system is implemented or an experiment is conducted, becomes more systematic and less ad hoc than it is otherwise.

In some ways the above may be read as an articulation of the “systems approach” or the procedure of “systems analysis.” This is not by accident. A number of contemporary philosophers of science have also contributed to the “systems” literature. A partial list of authors in this category includes Ackoff,^[50,51] Churchman,^[5,8,54,55] Helmer,^[56] and Rescher.^[57,58] The work of Mitroff^[59] is particularly interesting in this respect, especially his effort with Williams and Rathswohl,^[60] because it is frequently applied to information science topics.

Beyond the functioning of philosophy of science thought as an aid for the conceptualization of design issues and options, which is a function it has for all science, there

are a number of possibilities for the direct application of philosophy of science developments to the problem spaces of library and information sciences. The concept of “user,” for instance, is one that library and information scientists have discovered needs increasing precision. Library and information workers are frequently encouraged to actively consider and involve the “user” in the design of services first and in the delivery of services over time. Indeed, the attention that the concept of “user” has attracted in recent years can be said to account for the metamorphosis of the library and information sciences into the behavioral and social realms. To date, however, the language that the library and information profession has developed for discussing this concept is predominantly anecdotal in tone and descriptive in approach.

The concept of “user” can probably be said to have begun its ascendancy as people who work with information endeavored to make scientific sense of the associated concept of “relevance.” On both intuitional and evidential grounds, it is clear that the relevance of an item of information is a judgment made by a recipient of that item. The proposition is offered, then, that relevant items of information transform a passive recipient of information into an active user. A design objective that is consistent with this reasoning is that information delivery systems should strive for making *users* out of the *recipients* of their services. The manner in which these systems might do this, to come full circle, is to deliver highly relevant items of information.

In an article summarizing conclusions made from experimentation with relevance, Saracevic^[61] notes that comparisons of relevance judgments have been made among users, nonusers, experts, and nonexperts. The remark we want to make at this point is that such comparisons are quite obviously based upon a typology of recipients of information. This is to say that considering the degree of subject specialization of a recipient or the conditions of reception, an individual is typed, for purposes of analysis, as a user, nonuser, expert, or nonexpert. Referring back to our previous comment about the language that library and information scientists have for discussing the concept of user, we can now see exactly what that language is.

The hint of an alternative language, that is, an alternative typology, for discussing recipients and users of information can be recognized to reside in the philosophy of science thought we have surveyed. Assuming that library and information work will be concerned with scientific and technical communication for years to come, which is certainly true in part, the ways in which philosophers of science have come to discuss orientations assumed by scientists toward their work could be explored as a base for similar discussions among library and information scientists. This is to say that we would come to state information requirements and judgmental criteria of groups of recipients of information in terms of the degrees to which

they could be said to be rationalistic, empiricistic, and criticistic in their orientations. Although statements of this type are premature given current levels of development, we can suggest for purposes of illustration that the differential relevance of items of information could be systematically approached by assessing the rationalistic, empiricistic, and criticistic influence at work in the author and recipient.

Insofar as philosophies of science provide theories of science and of scientists, then, they allow two major areas of application to the library and information sciences to be pursued. Both of these have been discussed in the above. First of all, in summary, philosophies of science as theories of science help to make library and information scientists more aware of the constellation of approaches available for the execution of any given inquiry. Second, as theories of scientists, they contain characterizations of recipients and users of information to the extent that the information involved is that of scientific and technical communication. It is not to be concluded, however, that the philosophy of science is completely ready to be applied in these ways. There remains much work to be done by both philosophers and scientists.

SOME PRESENT AND FUTURE ISSUES

That which one regards as an “issue” in a field is that which is regarded as the problematic. It is the case, moreover, that the perception of the problematic is something that varies greatly from individual to individual. Everything we have said in this article pays tribute to this fact: what a rationalist takes for granted, an empiricist questions and vice versa. It has to be understood, therefore, that as we state some current and future issues in the following, these statements have to be interpreted, more than those of any other section of this article, in the light of the author’s point of view. Obviously, this point of view is not that of a philosopher of science per se; rather, it is that of an information scientist who has found material in the literature of the philosophy of science that provokes thought about and adds perspective to his work. In addition, the point of view of the author tends to be criticistic, that is, he favors the examination of the interaction of concepts and observations over the examination of concepts or observations by themselves.

Within this framework, it can be stated, preliminarily, that the major present and future issues of the philosophy of science are at the “fringes” of the field instead of at its core. In truth, it has to be acknowledged that this entire article has been on the fringes. Such “core issues” as laws versus empirical generalizations, the (a)symmetry of explanation and prediction, the structure of theories, and the explication of terms have occupied little space in the preceding. These core topics can be said to be focused on the *products* of science. Our focus can be said to have

been that of the *processes* attendant with the science. This consideration of processes attendant with science, moreover, is still a fringe concern for philosophers of science.

It is not fringe, however, for a number of other groups of scholars that we reference through the descriptor of the “sciences of science.” Such scholars have come to understand that a full treatment of the processes of science will require *at least* a politics, sociology, and psychology of science and scientists. Seminal works in this respect are those of Price^[62] and Maslow.^[63] Crane^[64] published a related effort, as has Mitroff.^[65] The monumental study by Freidson^[66] is also of interest, as are those of Hanson.^[4,38]

It is the case that many philosophers of science in modern times have systematically excluded the psychological from their sphere of inquiry. As he begins his milestone treatise on probability as inductive logic, Rudolf Carnap^[67] remarks at length on how it is inappropriate for a logician to attempt to speak to the point of the ways in which scientists actually do or even should reason. Logic and, so it seems, philosophy of science in this widespread conception should be neutral as to the actual practice of science. The core issues raised in this context are associated with the development of objective knowledge and the formulation of universal hypotheses and laws from time-bound experimentation. As is the situation with mathematics, the results of such research are presented as declarations of possibilities rather than imperatives for action.

In a certain sense, this attempt to define the core of the philosophy of science is similar to what some authors have tried to do with the issue of relevance in library and information science. Cooper,^[68] referencing Wilson,^[69] for instance, states clearly that his concern is that of *logical* relevance (topic-relatedness) rather than utility. King^[70] has also seen value in separating the psychological aspects of relevance from other aspects that could be considered. The main group of philosophers of science have placed such logical matters at the center of their specialization, as many library and information scientists can be said to have done with relevance.

The formal or “logico-mathematico” vein of philosophy of science has spawned a richly substantial literature. Recently, moreover, it has developed along lines that bring it into proximity with the library and information sciences. Some of the work in this class has been done by Kemeny,^[71] Watanabe,^[72] Hintikka and Suppes,^[73,74] and Suppes and Atkinson.^[75] The common ground involved here is bounded by inductive inference and information theory wherein information theory provides a “calculus” for certain measurement of language tasks associated with the procedures of inductive logic.

The neutrality of this style of philosophy of science can be said to be responsible for both its strength and its weakness. It has been strong because scholars devoted to it and working within it have been able to push forward without being constrained at every step by speaking to the

actualities of science and scientists. Note that this state of affairs, wherein philosophers of science have excluded behavioral and social inquiry from their approach, is symptomatic of a rationalistic frame of mind. This is the case even when the philosophers involved have been extolling the virtues of empiricism. But it is important to recognize that philosophers of science *do* philosophy and not science and, consequently, it is not inconsistent for them to use rationalistic arguments in philosophy for empiricistic conclusions in science.

There are those who are not convinced by this reasoning, and it is these that we have referred to as the fringe of the philosophy of science. We are at a point now from which we can understand clearly their position and the present author’s conception of the future. The fringe of the philosophy of science is constituted by those individuals who have adopted empirical methods for developing their philosophies. Evidently, they believe such philosophies are possible even though it can be expected that philosophy, psychology, and sociology may be radically transformed in the process. This is the area, the “empiricizing” of philosophy, in which interesting future issues will develop. It is the area in which interesting present issues have crystallized. The projected result is that the core of philosophy of science will itself transform to something that is more directly approachable and appropriate to scientists than that which is currently the case. Whether or not this transformation will also result in a philosophy that is too “vulgar” to attract the attention of competent philosophers is something that is difficult to decide.

Possibly the first and foremost group on this fringe of which we have made so much is that of the pragmatists. The reasons for this are not hard to guess. Philosophies can be characterized, as we have in the preceding to a limited extent, by their “unit of analysis.” Rationalism, for instance, analyzes things in terms of ideas, while empiricism uses sensations. Criticism’s interest is in the act of judgment and thus its emphasis is on the relation of idea and sense. The unit of analysis of pragmatism, which we have presented as the modern variant of criticism, is that of human action in general [see Mead,^[76] for instance] For pragmatists more than any other philosophers of science, therefore, the demand has been for an action-directed philosophy of science.

In addition to the push pragmatists have provided from the fringe, certain developments in the study of “objectivity” have set off some minor eruptions in the core itself. Primarily, it would seem, most of the problems are associated with the social sciences. Therein the appropriateness or even possibility of an objective comprehension of human and social behavior has been strongly questioned. Basically, the issue has come to be known as that of the “value-(non-) freedom” of the social sciences. Krimmerman’s anthology^[77] contains an excellent sampling of opinions on this subject. The biases that a social

scientist can introduce into an experiment have been the subject of study by Rosenthal,^[78–80] among others. To make the situation complicated many times again, moreover, it has been determined that the objectivity of social science research is in question due to biases introduced by *subjects* themselves. The classic case in point in this regard is that of the “Hawthorne Program” [which provided the material for a book by Roethlisberger and Dickson^[81,82]], wherein it was concluded that an improvement in industrial worker productivity and satisfaction could be traced to the workers’ participation in an announced experiment rather than to any alteration of the working environment.

No doubt to some, the problem of objectivity in the social sciences represents no less than a diagnosis of their inadequacy as sciences. Things, however, are not that simple. Astronomy, for instance, is certainly an “acceptable” science and yet astronomers have struggled for years (indeed, centuries) with the problem of consistency in observation. Such consistency would be, in principle, possible if objectivity of observation and reporting were operative. Physics, as viewed by Heisenberg,^[41] has evolved to a state of uncertainty in this respect as well. In an almost poetic chapter,^[41] Heisenberg outlines the dilemma of the physicist historically an expert in the realms of the obviously real (levers, inclined planes, pendula, etc.), approaching the atom and the awareness that with things atomic there is a world of “potentialities or possibilities rather than one of things or facts.” When the language of the physical sciences moves toward a potential or possible or probable calculus, it begins to sound similar to the dispositional or expectational or probable one of the social sciences.

So we find that the concept of objectivity, at the center of logico-mathematico strains of philosophy of science, is in a position of change of outlook. Modern physical science and modern social science have furnished evidence to the effect that objectivity is in the process of being replaced by intersubjectivity. Intersubjectivity, moreover, seems radically less a logical matter than one empirical insofar as the “inter-” of the concept requires attention be given to at least two things acting together rather than the solitary “ego” that can be found in so much of what we understand as logic. This is the major issue, though, that we have identified with the present and future of the philosophy of science. For purposes of summary, we again state that this issue, and all attendant issues, are those associated with the development of empirical techniques of philosophy in general and philosophy of science in particular.

CONCLUSION

The bibliographical sources for this article are extensive, and, thus, it may be of use to cite some works for purposes

of general reference. The author’s personal favorites, which is to say the ones that he consults most often, are those of Hanson,^[4,38] Turner,^[10] Churchman,^[8] Duhem,^[49] Kuhn,^[39,40] and Pepper.^[9] These are listed according to some measure of increasing difficulty. In the area of collections, the author favors those of Krimmerman^[77] and Brody.^[83] It can be noted that all of those references are from the twentieth century; it is the author’s opinion that it is best to start with these rather than the original, classic sources from which they draw.

Individuals who have not received citation in the preceding discussion but who have played influential roles in the development of contemporary philosophy of science thought are: Broad,^[84] Crombie,^[85] Eddington,^[86] Feigl,^[87] Feyerabend,^[88,89] Kaplan,^[90] Merleau-Ponty,^[91] Merton,^[92] Mill,^[93] Neurath,^[94] Pascal,^[95] Pearson,^[96] Popper,^[97,98] Quine,^[99] Reichenbach,^[100] Russell,^[101–103] Schlick,^[104] and Scriven.^[105] This list, however, should not be regarded as being exhaustive, for it reflects the scope of study of its author. The references given throughout this article also need not in every case be the most representative of an author although the attempt has been consciously made to meet such a condition for the majority.

ACKNOWLEDGMENT

The opportunity to prepare this article was extended to me by Ian I. Mitroff, University of Pittsburgh. Dr. Mitroff has been my philosophy of science mentor and I gratefully acknowledge his influence on my thinking.

Encyclopedia of Library and Information Sciences, Fourth Edition

Contents

Volume I

Academic Libraries / Susan Curzon and Jennie Quiñónez-Skinner	1
Accessibility / Lori Bell	14
Accreditation of Library and Information Studies Programs in the United States and Canada / Karen Lynn O'Brien	18
Acquisitions Institute at Timberline Lodge / Scott A. Smith	22
African Librarianship / Natalia T. Bowdoin and Janet Lee	33
Altmetrics / Richard Cave	44
American Association of Law Libraries (AALL) / Kate Hagan	48
American Association of Museums (AAM) / Elizabeth E. Merritt	56
American Association of School Librarians (AASL) / Donald C. Adcock	59
American Library Association (ALA) / Mary W. Ghikas	67
American Medical Informatics Association (AMIA) / Don E. Detmer, Tia Abner and Karen Greenwood	85
American National Standards Institute (ANSI) / Jana Zabinski	87
American Society for Information Science and Technology (ASIST) / Charles H. Davis and Debora Shaw	90
Approval Plans / Robert Nardini	96
Arab Federation for Libraries and Information (AFLI) / Nour Soufi	100
Archival Appraisal and Acquisition / Barbara Reed	105
Archival Arrangement and Description / Joanne Evans, Sue McKemmish and Barbara Reed	115
Archival Documentation / Gavan McCarthy and Joanne Evans	127
Archival Finding Aids / Su Kim Chung and Karla Irwin	133
Archival Management and Administration / Michael J. Kurtz	141
Archival Reference and Access / Mary Jo Pugh	149
Archival Science / Elizabeth Shepherd	166
Archives / Adrian Cunningham	179
Archivists and Collecting / Richard J. Cox	195
Area and Interdisciplinary Studies Literatures and Their Users / Lynn Westbrook	209
ARMA International, Inc. / Carol E. B. Choksy	221
Armenia: Libraries, Archives, and Museums / Sylva Natalie Manoogian	228
Art Galleries / Daniel C. Danzig	241
Art Librarianship / Kathryn M. Wayne	249
Art Museums / David Gordon	259

Volume I (*cont'd.*)

Artificial Intelligence / Jianhua Chen	269
Artificial Neural Networks and Natural Language Processing / Hermann Moisl	279
Arts Literatures and Their Users / Lisl Zach	293
ASLIB / David Bawden and Lyn Robinson	301
Association for Information Science and Technology / Diane H. Sonnenwald, Charles H. Davis and Debora Shaw	311
Association for Information Systems (AIS) / William R. King and Dennis Galletta	318
Association for Library Collections and Technical Services / Charles Wilt	324
Association for Library Service to Children (ALSC) / Virginia A. Walter	333
Association of College and Research Libraries (ACRL) / Mary Ellen Davis and Mary Jane Petrowski	338
Association of Library Trustees, Advocates, Friends and Foundations (ALTAFF) / Sally Gardner Reed	361
Association of Research Libraries (ARL) / Lee Anne George and Julia Blixrud	364
Association of Specialized and Cooperative Library Agencies (ASCLA) / Barbara A. Macikas	376
Australia: Libraries, Archives, and Museums / Alex Byrne	379
Australian Library and Information Association (ALIA) / Sue Hutley, Jane Hardy and Judy Brooker	396
Authentication and Authorization / David Millman	401
Automated Acquisitions / Patricia A. Smith and Allison V. Level	408
Automatic Abstracting and Summarization / Daniel Marcu	418
Automatic Discourse Generation / John A. Bateman	430
Back-of-the-Book Indexing / Nancy C. Mulvany	440
Bibliographic Control [ELIS Classic] / Robert L. Maxwell	447
Bibliographical Society (London) / Julian Roberts	456
Bibliographical Society of America (BSA) / Hope Mayo	463
Bibliography / D. W. Krummel	468
Bibliometric Overview of Information Science / Howard D. White	480
Bibliometric Research: History [ELIS Classic] / Dorothy H. Hertzfel	492
Bibliothèque Nationale de France / Noémie Lesquins	531
Binding [ELIS Classic] / Lawrence S. Thompson	538
Biological Information and Its Users / Kalpana Shankar	554
Blind and Physically Disabled: Library Services / Jane Rosetta Virginia Caulton and Stephen Prine	563
Bliss Bibliographic Classification First Edition [ELIS Classic] / Jack Mills	573
Bliss Bibliographic Classification Second Edition / Vanda Broughton	581
Boolean Algebras [ELIS Classic] / A. R. Bednarek	591
Brazil: Library Science / Mariza Russo	597
Brazil: Library Science—Distance Education / Mariza Russo	603
Brazil: Museums / Regina Dantas and Pamela Howard-Reguindin	611
British Library / Andy Stephens	616
Business Informatics / Markus Helfert	630
Business Information and Its Users / Eileen G. Abels	635
Business Literature: History [ELIS Classic] / Edwin T. Coman, Jr.	643
Canada: Libraries and Archives / Ian E. Wilson and Sean F. Berrigan	654
Canadian Heritage Information Network (CHIN) / Shannon Ross and Paul M. Lima	675
Canadian Library Association (CLA) / Donald I. Butcher	681
Careers and Education in Archives and Records Management / Karen Anderson	685
Careers and Education in Information Systems / Paul Gray and Lorne Olfman	693

Volume I (*cont'd.*)

Careers and Education in Library and Information Science / <i>Jana Varlejs</i>	706
Careers and Education in Records and Information Management / <i>Carol E. B. Choksy</i>	715

Volume II

Cataloging / <i>Daniel N. Joudrey</i>	723
Cataloging Cultural Objects (CCO) / <i>Elizabeth O'Keefe and Maria Oldal</i>	733
Catalogs and Cataloging: History [<i>ELIS Classic</i>] / <i>Eugene R. Hanson and Jay E. Daily</i>	743
Censorship and Content Regulation of the Internet / <i>Peng Hwa Ang</i>	780
Center for Research Libraries / <i>Mary I. Wilke</i>	789
Charleston Conference / <i>Katina Strauch</i>	794
Chartered Institute of Library and Information Professionals (CILIP) / <i>Tim Owen</i>	806
Chemistry Literature and Its Users [<i>ELIS Classic</i>] / <i>Judith N. Currano</i>	814
Chemoinformatics / <i>Peter Willett</i>	830
Children and Information Technology / <i>June Abbas</i>	839
Children's Literature / <i>Judith V. Lechner</i>	852
Children's Services in Libraries / <i>Virginia A. Walter and Melissa Gross</i>	876
China: Libraries, Archives, and Museums / <i>Priscilla C. Yu and TzeHuey Chiou-Peng</i>	886
Circulation Services / <i>Vanessa Irvin and Jeff E. Bullard</i>	916
Citation Analysis / <i>Howard D. White</i>	923
Citation Indexes and the <i>Web of Science</i> / <i>Marie E. McVeigh</i>	940
Citer Motivations [<i>ELIS Classic</i>] / <i>Terrence Brooks</i>	951
Classification Theory / <i>Clare Beghtol</i>	958
Clinical Decision-Support Systems / <i>Kai Zheng</i>	974
College Libraries / <i>Thomas G. Kirk, Jr.</i>	983
Communication and Communication Studies / <i>Brenda Dervin and CarrieLynn D. Reinhard</i>	994
Communication Policy: United States / <i>D. Linda Garcia</i>	1007
Community Informatics / <i>Kate Williams and Joan C. Durrance</i>	1027
Complexity and Self-Organization / <i>Francis Heylighen</i>	1034
Computer-Mediated Communication (CMC) / <i>Michael A. Chilton and Roger McHaney</i>	1044
Computer-Supported Cooperative Work (CSCW) / <i>Kevin L. Mills</i>	1053
Conservation and Preservation of Museum Objects / <i>Ellen Pearlstein</i>	1068
Controlled Vocabularies for Art, Architecture, and Material Culture / <i>Murtha Baca</i>	1076
Corporate Archives / <i>Philip Mooney</i>	1081
Corporate Art Collections / <i>Laura Matzer</i>	1086
Corporate Information Centers / <i>Barbara M. Spiegelman and Nancy Flury Carlson</i>	1094
Corporate Records Management / <i>Barbara M. Cross and Barbara E. Nye</i>	1104
Credibility and Cognitive Authority of Information / <i>Soo Young Rieh</i>	1113
Croatia: Libraries, Archives, and Museums / <i>Aleksandra Horvat, Josip Kolanović and Višnja Zgaga</i>	1121
CrossRef Publisher Linking Network / <i>Amy E. Brand</i>	1132
Cultural Memory / <i>Robert DeHart</i>	1139
Curating Archaeological Artifacts / <i>Alex W. Barker</i>	1147
Curating Natural History Collections / <i>Kimberly S. Bostwick</i>	1156
Custody and Chain of Custody / <i>Bernadette G. Callery</i>	1164
Data and Data Quality / <i>Thomas C. Redman and Christopher Fox and Anany Levitin</i>	1171
Deaf and Hearing Impaired: Communication in Service Contexts [<i>ELIS Classic</i>] / <i>Warren R. Goldmann</i>	1183

Volume II (*cont'd.*)

Decision Sciences / <i>Sven Axsäter and Johan Marklund</i>	1192
Decision Support Systems / <i>Marek J. Druzdzel and Roger R. Flynn</i>	1200
Demand-Driven Acquisition/Patron-Driven Acquisition / <i>Michael Levine-Clark</i>	1209
Denmark: Libraries, Archives, and Museums / <i>Jens Thorhauge, Jakob Heide Petersen and Ole Magnus Mølbak Andersen</i>	1215
Descriptive Cataloging Principles / <i>Elena Escolano Rodríguez</i>	1229
Design Science in the Information Sciences / <i>Judith Weedman</i>	1242
Dewey Decimal Classification (DDC) / <i>Joan S. Mitchell and Diane Vizine-Goetz</i>	1256
Digital Content Licensing / <i>Paul D. Callister and Kathleen Hall</i>	1267
Digital Divide and Inclusion / <i>Mark Warschauer and Melissa Niiya</i>	1279
Digital Humanities / <i>Julia Flanders and Elli Mylonas</i>	1286
Digital Humanities and Academic Libraries / <i>Bobby Smiley and Michael Rodriguez</i>	1298
Digital Images / <i>Melissa Terras</i>	1307
Digital Millennium Copyright Act of 1998 / <i>Jonathan A. Franklin</i>	1316
Digital Object Identifier (DOI®) System / <i>Norman Paskin</i>	1325
Digital Preservation / <i>Jacob Nadal</i>	1332
Diplomatics / <i>Luciana Duranti</i>	1338
Disaster Planning and Recovery for Cultural Institutions / <i>Sheryl Davis, A. Patricia Smith-Hunt and Kristen Kern</i>	1347
Document Information Systems / <i>K. van der Meer</i>	1360
Document Theory / <i>Niels Windfeld Lund and Roswitha Skare</i>	1372
Document Type Definition (DTD) / <i>Judith Wusteman</i>	1381
Dublin Core Metadata Initiative (DCMI): A Personal History / <i>Stuart L. Weibel</i>	1390
Economics Literature: History [ELIS Classic] / <i>Arthur H. Cole and Laurence J. Kipp</i>	1399
Electronic Records Preservation / <i>Robert P. Spindler</i>	1413
Electronic Resources & Libraries (ER&L) / <i>Jesse Koennecke</i>	1419
Encoded Archival Description / <i>Daniel Pitti and Michael Rush</i>	1423
Engineering Literatures and Their Users [ELIS Classic] / <i>Thomas E. Pinelli, Ann P. Bishop, Rebecca O. Barclay and John M. Kennedy</i>	1433

Volume III

Epistemology / <i>Paul K. Moser</i>	1455
Ethical and Legal Aspects of Archival Services / <i>Sara S. Hodson</i>	1463
Ethical Aspects of Library and Information Science / <i>Richard Rubin and Thomas J. Froehlich</i>	1469
Ethical Issues in Information Systems / <i>Vladimir Zwass</i>	1484
Ethiopia: Libraries, Archives, and Museums / <i>Shiferaw Assefa</i>	1494
Everyday Life Information Seeking / <i>Reijo Savolainen</i>	1506
Evidence-Based Practice / <i>Prudence W. Dalrymple</i>	1516
Exhibition Design / <i>Lee H. Skolnick, Dan Marwit and Jo Ann Secor</i>	1523
Facet Analysis [ELIS Classic] / <i>Douglas J. Foskett</i>	1534
Faceted Application of Subject Terminology (FAST) / <i>Eric R. Childress and Diane Vizine-Goetz</i>	1539
Federal Electronic Information in the United States / <i>Carol D. Doyle</i>	1549
Film and Broadcast Archives / <i>Karen F. Gracy and Karen E. King</i>	1560
Film Archiving: History / <i>Steve Ricci</i>	1584
France: Archives, Museums, and Libraries / <i>Martine Poulain</i>	1589

Volume III (*cont'd.*)

Functional Requirements for Subject Authority Data (FRSAD): Conceptual Model / <i>Marcia Lei Zeng, Athena Salaba and Maja Žumer</i>	1606
Fuzzy Set Theory / <i>Donald Kraft, Gloria Bordogna and Gabriella Pasi</i>	1618
Games and Gaming / <i>Diane Robson and Breanne A. Kirsch</i>	1636
Genealogical Literature and Its Users / <i>Mavis B. Molto</i>	1644
Genre Theory and Research / <i>Catherine F. Schryer</i>	1662
Geographic Information Systems (GIS) / <i>Timothy F. Leslie and Nigel M. Waters</i>	1671
Geographical Literature: History [ELIS Classic] / <i>Nora T. Corley</i>	1683
Germany: Libraries, Archives, and Museums / <i>Claudia Lux</i>	1693
Global Open Knowledgebase / <i>Kristen Wilson</i>	1710
Government Documents: Collection and Management / <i>Aimée C. Quinn, Lori Smith and James Church</i>	1715
Greece: Archives / <i>Nestor Bamidis</i>	1728
Greece: Libraries / <i>Anestis Sitas and Mersini Moreleli-Cacouris</i>	1733
Greece: Museums / <i>Maria Economou</i>	1741
Grey Literature [ELIS Classic] / <i>Joachim Schöpfel and Dominic J. Farace</i>	1746
HathiTrust / <i>Rick Anderson</i>	1757
Health Science Professional Literatures and Their Users / <i>Cheryl Dee and Jocelyn Rankin</i>	1763
Historical and Archaeological Sites: Development and Preservation / <i>Robert B. Pickering</i>	1771
Historical Societies / <i>Mark Sgambettera</i>	1779
Historical Sources and Their Users / <i>Margaret Stieg Dalton</i>	1786
History of Libraries / <i>John Mark Tucker and Edward A. Goedecken</i>	1796
History of Museums / <i>John Edward Simmons</i>	1812
History of Paper / <i>Sidney E. Berger</i>	1824
History of Public Libraries [ELIS Classic] / <i>Frank B. Sessa</i>	1836
History of Records and Information Management / <i>William Benedon</i>	1850
History of the Book / <i>Jonathan Rose</i>	1859
History: Three Basic Printing Processes / <i>Sidney E. Berger</i>	1865
Hospital Libraries / <i>Rosalind K. Lett</i>	1870
Human–Computer Interaction Research in Information Retrieval / <i>Shin-jeng Lin</i>	1895
Humanities Literatures and Their Users / <i>Stephen E. Wiberley, Jr.</i>	1909
Hungary: Libraries, Archives, and Museums / <i>Katalin Radics</i>	1917
Hypertext and Hypercard: Early Development [ELIS Classic] / <i>Susan K. Kinnell and Carl Franklin</i>	1935
Illumination [ELIS Classic] / <i>Abdul Moid</i>	1945
Impact Assessment of Cultural Institutions / <i>Sara Selwood</i>	1958
Incunabula [ELIS Classic] / <i>John P. Immroth and Romano Stephen Almagno</i>	1966
Indexing: History and Theory / <i>Bella Hass Weinberg</i>	1978
India: Libraries, Archives and Museums / <i>Krishan Kumar, V. Jeyaraj and Ramesh C. Gaur</i>	1992
Indigenous Librarianship / <i>Kathleen Burns, Ann Doyle, Gene Joseph and Allison Krebs</i>	2031
Information / <i>Marcia J. Bates</i>	2048
Information Arts / <i>Christiane Paul and Jack Toolin</i>	2064
Information Behavior / <i>Marcia J. Bates</i>	2074
Information Behavior Models / <i>Thomas D. Wilson</i>	2086
Information Crises and Crisis Information / <i>Philippe Baumard</i>	2094
Information Explosion / <i>Ronald E. Day</i>	2101
Information Management / <i>Brian Detlor</i>	2106
Information Needs / <i>Charles M. Naumer and Karen E. Fisher</i>	2115

Volume III (*cont'd.*)

Information Needs and Behaviors of Diasporic Populations / <i>Ajit K. Pyati</i>	2122
Information Needs and Behaviors of Populations in Less Developed Regions / <i>Innocent I. Ekoja</i>	2130
Information Policy: European Union / <i>Debbie Rabina and Scott Johnston</i>	2138
Information Policy: United States / <i>Peter Hernon and Harold C. Relyea</i>	2147
Information Practice / <i>Crystal Fulton and Jean Henefer</i>	2162
Information Retrieval Experimentation [ELIS Classic] / <i>Jean Tague-Sutcliffe</i>	2172

Volume IV

Information Retrieval Protocols: Z39.50 and Search and Retrieve via URL / <i>William Moen</i>	2181
Information Retrieval Support Systems / <i>Yiyu Yao, Ning Zhong and Yi Zeng</i>	2192
Information Retrieval Systems / <i>Ray R. Larson</i>	2199
Information Scattering / <i>Suresh K. Bhavnani and Concepción S. Wilson</i>	2210
Information Science / <i>Tefko Saracevic</i>	2216
Information Search Process (ISP) Model / <i>Carol Collier Kuhlthau</i>	2232
Information Searching and Search Models / <i>Iris Xie</i>	2239
Information Society / <i>Frank Webster</i>	2253
Information Systems / <i>E. Burton Swanson</i>	2272
Information Systems Failure / <i>Chris Sauer and Gordon B. Davis</i>	2280
Information Technology Adoption / <i>Conrad Shayo</i>	2290
Information Technology Literacy / <i>James W. Marcum and Denise I. O'Shea</i>	2303
Information Technology Project Implementation in Developing Countries [ELIS Classic] / <i>Athanase B. Kanamugire</i>	2312
Information Technology Standards for Libraries [ELIS Classic] / <i>Christinger Tomer</i>	2341
Information Theory / <i>Paul B. Kantor</i>	2350
Information Use for Decision Making / <i>Edward T. Cokely, Lael J. Schooler and Gerd Gigerenzer</i>	2359
Informetrics / <i>Judit Bar-Ilan</i>	2367
Institutional Records and Archives / <i>David Farneth</i>	2377
Intellectual Freedom and the American Library Association (ALA): Historical Overview [ELIS Classic] / <i>Judith F. Krug</i>	2387
Intelligence and Security Informatics / <i>Hsinchun Chen, Zhenhua Lai, Yan Dang and Yulei Zhang</i>	2398
International and Comparative Librarianship / <i>Peter Johan Lor</i>	2404
International Association of Sound and Audiovisual Archives (IASA) / <i>Ilse Assmann</i>	2413
International Association of Technological University Libraries (IATUL) / <i>Nancy Fjällbrant and Alice Trussell</i>	2418
International Communication Association (ICA) / <i>Ronald E. Rice</i>	2421
International Council of Museums (ICOM) / <i>Patrick J. Boylan</i>	2429
International Council on Archives (ICA) / <i>Perrine Canavaggio and Marcel Caya</i>	2437
International Council on Knowledge Management (ICKM) / <i>Franz Barachini</i>	2445
International Federation of Library Associations and Institutions (IFLA) / <i>Ross Shimmer,</i> <i>Peter Johan Lor, Sofia Kapnisi, Sjoerd Koopman and Stuart Hamilton</i>	2451
International Federation of Television Archives (FIAT/IFTA) / <i>Steve Bryant</i>	2465
International Organization for Standardization (ISO) / <i>Alan Bryden and Catherine Dhérent</i>	2470
International Records Management Standards ISO 15489 and 23081 / <i>Barbara Reed</i>	2481

Volume IV (*cont'd.*)

International Records Management Trust / <i>Anne Thurston</i>	2487
International Society for Knowledge Organization (ISKO) / <i>Ingetraut Dahlberg</i>	2494
Internet Genres / <i>Kevin Crowston</i>	2503
Internet Search Tools: History to 2000 / <i>Dale J. Vidmar and Connie J. Anderson-Cahoon</i>	2516
InterPARES / <i>Luciana Duranti</i>	2526
iSchools / <i>Ronald L. Larsen</i>	2536
Israel: Libraries, Archives, and Museums / <i>Snunith Shoham and Silvia Schenkolewski-Kroll</i>	2542
Japan: Libraries, Archives, and Museums / <i>Masaya Takayama, Yoriko Miyabe, Toru Koizumi and Hiroyuki Hatano</i>	2560
Kazakhstan: Libraries, Archives, and Museums / <i>Leslie Champeny, Joseph Luke, Anna Bergaliyeva and Olga Zaitseva</i>	2578
Kenya: Libraries, Museums, and Archives / <i>Irene Muthoni Kibandi, Pancras Kimaru, Caroline Kayoro, Philomena Kagwiria Mwirigi, Sophie Ndegwa, Nelson Otieno Karilus, Charles Nzivo, Linda Mboya and Lilian Gisesa</i>	2592
Knowledge / <i>Paul K. Moser and Arnold vander Nat</i>	2610
Knowledge Creation and Use in Organizations / <i>Maija-Leena Aulikki Huotari and Anna Suorsa</i>	2618
Knowledge Discovery in Data Streams / <i>Xuan Hong Dang and Kok-Leong Ong</i>	2626
Knowledge Management / <i>Kimiz Dalkir</i>	2640
Knowledge Management Systems / <i>Dick Stenmark</i>	2649
Knowledge Management: Early Development / <i>Michael Koenig and Ken Neveroski</i>	2657
Knowledge Organization System Standards / <i>Stella G. Dextre Clarke</i>	2665
Knowledge: Tacit and Explicit / <i>Philippe Baumard</i>	2677
Latent Semantic Indexing / <i>Dian I. Martin and Michael W. Berry</i>	2688
Latinos and U.S. Libraries: History / <i>Romelia Salinas</i>	2698
Law Firm Librarianship / <i>Brenda A. Burton, Mary B. Eggert and Clara C. Mosquera</i>	2705
Law Librarianship / <i>Richard A. Danner, Mark E. Estes and Judith Adams Meadows</i>	2710
Law Literature and Its Users / <i>Penny Hazelton</i>	2733
Learning and Information Seeking / <i>Louise Limberg and Mikael Alexandersson</i>	2751
Libraries / <i>Jennifer Weil Arns</i>	2762
Library and Information Science / <i>Miriam E. Sweeney and Leigh S. Estabrook</i>	2768
Library and Information Technology Association (LITA) / <i>Rachel E. Vacek</i>	2775
Library Anxiety / <i>Diane Mizrahi</i>	2782
Library Architecture and Design / <i>Charlene S. Hurt and Thomas L. Findley</i>	2788
Library Architecture: History / <i>Nan Christian Ploug Dahlkild</i>	2797
Library Automation: History / <i>Robert M. Hayes</i>	2810
Library Consortia in Europe / <i>Tommaso Giordano</i>	2822
Library Fundraising and Development / <i>Susan K. Martin</i>	2832
Library Leadership and Management Association (LLAMA) / <i>Robert Allen Daugherty</i>	2841
Library of Congress Classification (LCC) / <i>Lois Mai Chan and Theodora L. Hodges</i>	2847
Library of Congress Genre/Form Terms for Library and Archival Materials / <i>Janis L. Young</i>	2856
Library of Congress Subject Headings (LCSH) / <i>Janis L. Young</i>	2866
Library of Congress: History / <i>John Y. Cole</i>	2879
Library Portals and Gateways / <i>Frank Cervone</i>	2892
Library Publishing Initiatives: North America / <i>Katherine Skinner and Sarah Lippincott</i>	2901

Volume V

Library Science in the United States: Early History / <i>John V. Richardson, Jr.</i>	2909
Library Technical Services / <i>Doris S. Helfer and Helen Heinrich</i>	2918
Linguistics and the Information Sciences / <i>John C. Paolillo</i>	2927
Linked Data / <i>Jeremy Myntti</i>	2938
Lithuania: Libraries and Librarianship / <i>Elena Macevičiūtė</i>	2943
Louvre / <i>Bette W. Oliver</i>	2958
Machine Readable Cataloging (MARC): 1961–1974 [ELIS Classic] / <i>Henriette D. Avram</i>	2963
Machine Readable Cataloging (MARC): 1975–2007 / <i>Sally H. McCallum</i>	2980
Makerspaces in Libraries / <i>Patrick Tod Colegrove</i>	2990
Management of Very Large Distributed Shared Collections [ELIS Classic] / <i>Reagan W. Moore</i>	2997
Managing an Information Business / <i>Gloria Dinerman</i>	3004
Marketing Library and Information Services / <i>Dinesh K. Gupta and Réjean Savard</i>	3011
Mathematics Literature: History [ELIS Classic] / <i>Barbara Schaefer</i>	3019
Medical Library Association (MLA) / <i>Carla J. Funk</i>	3033
Medical Literature: History [ELIS Classic] / <i>William K. Beatty</i>	3041
Metadata and Digital Information [ELIS Classic] / <i>Jane Greenberg</i>	3058
Metamarkup Languages: SGML and XML / <i>Airi Salminen</i>	3072
Mexico: Libraries, Archives, and Museums / <i>Jesús Lau</i>	3082
Modeling Documents in Their Context / <i>Airi Salminen</i>	3105
Moldova: Archives, Museums, and Libraries / <i>Hermina G.B. Anghelescu,</i> <i>Silviu Andrieș-Tabac and Elena Ploșniță</i>	3117
Moving Image Indexing / <i>James M. Turner</i>	3129
Multilingual Information Access / <i>Douglas W. Oard</i>	3140
Museum Accreditation Program / <i>Leah Arroyo and Julie Hart</i>	3146
Museum Architecture and Gallery Design / <i>Volker M. Welter</i>	3148
Museum Collecting and Collections / <i>Robert B. Pickering</i>	3161
Museum Computer Network (MCN) / <i>Marla Misunas and Richard Urban</i>	3170
Museum Informatics / <i>Paul F. Marty</i>	3176
Museum Management / <i>Gary Edson</i>	3185
Museum Registration and Documentation / <i>Dixie Neilson</i>	3199
Museum Studies / <i>Marjorie Schwarzer</i>	3214
Museum Web Sites and Digital Collections / <i>David Bearman and Jennifer Trant</i>	3222
Museums / <i>Leslie Madsen-Brooks</i>	3233
Museums and Community / <i>Tamara Biggs</i>	3243
Museums and Their Visitors: Historic Relationship / <i>Samuel J. Redman</i>	3251
Museums as Place / <i>Peter Davis and Han-Yin Huang</i>	3258
Music Information Retrieval / <i>Kjell Lemström and George Tzanetakis</i>	3267
Music Librarianship / <i>Holly Gardinier, Sarah R. Canino and Carl Rahkonen</i>	3275
Name Authority Control / <i>Janifer Gatenby and Karen Smith-Yoshimura</i>	3288
National Archives / <i>Helen Forde</i>	3298
National Biological Information Infrastructure (NBII) / <i>P. Bryan Heidorn and Annette Olson</i>	3306
National Historical Publications and Records Commission (NHPRC) / <i>Keith Donohue</i>	3315
National Libraries / <i>Ian McGowan</i>	3320
National Library of Medicine / <i>Kathel Dunn</i>	3334
Natural Language Processing for Information Retrieval / <i>Elizabeth D. Liddy</i>	3346
Network Management / <i>Robert J. Sandusky</i>	3356

Volume V (*cont'd.*)

Network of European Museum Organisations (NEMO) / Frank Birkebæk	3365
Networked Knowledge Organization Systems/Services (NKOS) / Marianne Lykke	3366
New Zealand Aotearoa: Libraries / Heather M. Lamond	3371
Non-governmental Organizations and Information / Lynne M. Rudasill and Steve W. Witt	3380
North American Serials Interest Group / Jill Emery	3388
OCLC: A Worldwide Library Cooperative / Jay Jordan	3392
Older Adults' Information: Needs and Behavior / Kirsty Williamson and Terry Asla	3406
One-Person Libraries / Judith A. Siess	3413
Online Catalog Subject Searching / Danny C.C. Poo and Christopher S.G. Khoo	3422
Online Library Instruction / Beth Evans	3432
Online Public Access Catalogs (OPACs) [ELIS Classic] / Kevin Butterfield	3450
Ontologies and Their Definition / Jos de Bruijn and Dieter Fensel	3455
Open Access Scholarship and Publishing / Malcolm Getz	3465
Open Archival Information System (OAIS) Reference Model / Christopher A. Lee	3477
Open Source Software / Michael Tiemann	3488
Oral History in Libraries and Archives / Debra Gold Hansen	3494
ORCID / Laurel L. Haak	3505
Organization Theories / Evelyn Daniel	3510
Organizational Culture / Gunilla Widén-Wulff	3520
Organizational Learning / Erica Wiseman	3526

Introduction to the Encyclopedia of Library and Information Sciences, Fourth Edition

How to Use This Encyclopedia

Entries are arranged alphabetically in this encyclopedia (see end papers for alphabetical list). The editors of this edition (ELIS-4) have decided to forego the Topical Table of Contents that was provided in ELIS-3 by editors Marcia Bates and Mary Niles Maack. At the time of publication of ELIS-3, the Topical TOC was crucial for readers to get a sense of how subjects were grouped and an understanding of the field or subfield through the clustering of categorical entries in the print edition. ELIS-4 is envisioned as a primarily online reference work where a Topical TOC does not serve the same purpose. The print edition is served well by the main TOC as well as the detailed index, while entries in the online version are easily discoverable through title, author, keyword, and full text searches.

In sum, relevant entries can be found by

1. Entry title (alphabetical arrangement of entries in the encyclopedia or listing in the end papers)
2. Specific name or keyword, including the index at the end of each volume

If the first name or keyword searched is not found, try several more variations—either different words or a different order of words. Most topics are described in several ways in the literature of a discipline, and the first term or phrase that comes to mind may not be the one used here.

Scope of the Encyclopedia

The title of the third edition, *Encyclopedia of Library and Information Sciences*, ended with the letter “s” because the encyclopedia was broadened to cover a spectrum of related and newly emerging information disciplines, including archival science, document theory, informatics, and records management, among others. The fourth edition continues this trend but with an extensive focus on the aspects of library and information sciences that have been heavily impacted by the adoption and reliance on online information distribution. This focus is reflected in the inclusion of numerous new entries such as digital preservation, altmetrics, web-scale discovery services, demand-driven acquisitions, and global open knowledgebases. Alongside these entries based on entirely new topics, the expanded use of the Internet for information has led to new treatment of traditional LIS topics such as resource description and access (RDA) that reflects the adoption of new standards for cataloging.

ELIS-4 also seeks to build upon the description of professional practice to round out the theoretical perspective that previous editions covered very well. Both current editors are academic research librarians and thus, focused heavily on addressing gaps in the encyclopedia related to academic research information while still relying heavily on the structure established by editors of ELIS-3. For example, ELIS-3 introduced country profiles and ELIS-4 builds upon that with new entries for New Zealand and a third on Brazil, in addition to revisions for Slovakia, Netherlands, Canada, Belarus, Kazakhstan, and Brazil among others. This edition also expands the number of entries for named cultural and information entities that did not appear in previous editions, such as the National Library of Medicine, North American Serials Interest Group (NASIG), the International Association of Scientific, Technical and Medical Publishers (STM), and ASLIB, as well as entities like the HathiTrust that have been established since the last edition was published. A number of new entries describing important information conferences such as the Acquisitions Institute at Timberline, the Charleston Conference, and Electronic Resources in Libraries (ER&L) also help round out the encyclopedia and further the description of the current state of academic research librarianship.

ELIS-4 also continues the tradition of designating important entries of historical or theoretical importance as “ELIS Classics.” These are entries by major figures in the library and information sciences or those that describe core concepts in LIS theory, practice, or education that appeared in earlier editions of the encyclopedia. The current editors preserved the approximately 40 previous “ELIS Classics” and designated 13 previous entries as new “ELIS Classics.”

There are more than 550 entries, of which more than 20 are new, another 93 are revisions to prior entries that have been brought up to date by their authors or by new authors, about 30 are ELIS Classics, and about 400 are reprinted from an earlier edition since they have remained relevant to the present. It is important to note that the editors also had to make some choices related to retiring entries that were no longer relevant—due to the passage of time and the development of the field, the technologies and theories described in those entries were deemed to be out of scope for the new edition and thus not revised or reprinted.

Encyclopedia Authors

As in past editions, the authors writing for the encyclopedia are major researchers, librarians and practitioners, and leaders in the fields and subfields in the disciplines in which they are writing. Noted scholars are well represented, and a number of authors are former leaders in LIS associations, including the American Library Association (ALA), the Association for College and Research Libraries (ACRL), the International Federation of Library Associations and Institutions (IFLA), the American Society for Information Science and Technology (ASIS&T), and the American Association of Library and Information Science Education (ALISE). In addition, there are many contributors who are current or former directors of major institutions. As in past editions, the editors are very proud of the range and diversity of authors who have written these entries for the encyclopedia and we thank them for sharing their expertise with the current and future readers and researchers in the field.

Finally, the editors for ELIS-4 have grappled with the challenges of entry generation that was noted by previous editors in nearly every edition: that not all ideas, topics, and potential entries were able to be completed for publication in this edition. While we made a valiant attempt to include entries identified by ELIS-3 editors but not secured for publication in that edition, we sometimes could not find authors willing to take those topics on. Similarly, we were sometimes unable to secure revisions to entries from new authors when previous authors were unable to perform that task. To the greatest extent possible, we endeavored to replace authors when entries were deemed important enough to appear in ELIS-4 but initial or previous authors had to decline or defaulted. No doubt, the editors of ELIS-5 will also pick up the mantle and attempt to round out the encyclopedia with entries for anything that ELIS-4 missed. As noted by editors Bates and Niles Maack in ELIS-3, this problem of missing topics was also acknowledged by Allen Kent, editor of the first edition of ELIS. Kent stated in 1973, "I have prepared this presentation to make sure the lessons of Diderot-d'Alembert are recalled in terms of encyclopedia-making as an exercise in the art of the possible."

Background and Development of the Encyclopedia

The first edition of ELIS, under the editorship principally of Allen Kent and Harold Lancour, was published between 1968 and 1982. The 33 volumes of the first edition were published in alphabetical sequence during those years. After the "Z" volume appeared in 1982, a number of supplements were published at roughly the rate of two per year, up to and including volume 73, which appeared in 2003. Miriam Drake was appointed editor for the second edition, which appeared in 2003, both online and in paper. The second edition came out at one time in four large-format volumes, with a supplement in 2005 [3]. Kent and Lancour covered a wide range of librarianship, information science, and some computer science topics. Drake, an academic library director, emphasized academic libraries, and the ELIS-2 volumes contained many profiles of major academic libraries and professional library associations.

The third edition, under the editorship of Marcia Bates and Mary Niles Maack, reflected a growing convergence among the several disciplines that concern themselves with information and the cultural record. As information science educators and noted researchers in the field, their focus was on growing the encyclopedia in the theoretical fields of information sciences as well as drawing together the associated information and cultural disciplines such as archival sciences and museum studies within the overall field of LIS.

For this edition, we have focused on developing the encyclopedia to reflect the changing nature of information production and consumption through online and digital forms. We have also endeavored to fill in gaps in the description of important people, places, and theories in the information sciences, and further enhanced the description of important concepts related to the provision of research information and the field's major institutions.

We continue to see the audience for the encyclopedia just as previous editors have: as principally consisting of 1) the educated lay person interested in one or more of its topics, 2) students learning about a topic, and 3) professionals and researchers in the several fields who want to learn about something new, or to be refreshed on a familiar topic.

We honored the previous editors by reengaging their superb Editorial Advisory Board with significant new additions of experts known to the current editors. (See listing in the front matter.) These leaders and experts from as many disciplines as are in the encyclopedia provided excellent guidance and feedback for the editors as they began the process of new topic generation, evaluation of previous entries, and offering to author or review numerous entries throughout the process of publication.

All new and revised entries were reviewed by one or more outside expert reviewer as well as one or more of the editors. Referees provided invaluable feedback to authors, including noting errors or omissions as well as making suggestions on additional aspects of the topic to cover. While we made every reasonable attempt through this process to check the accuracy of every entry and every fact, undoubtedly readers will find some topics explained more thoroughly or accurately than others. Indeed, due to the time frame from the beginning of the generation of the fourth edition and the time of publication, readers will reasonably note that some topics have been quickly superseded due to this passage of time, so the

date of acceptance of the entry will be noted on each entry since several years may have passed since the writing of the entry and the publication of this edition.

Acknowledgments

This edition of the encyclopedia was possible only through the countless hours that the editors, John McDonald and Michael Levine-Clark, spent reviewing the previous encyclopedia entries, outlining the topics that were missing or that were newly emerging in the field, and identifying appropriate expert authors to write those new entries. In addition, the editors devoted extensive time to corresponding with previous authors encouraging them to revise their entries, and finding replacement authors for important entries that needed revisions but whose original authors were unavailable.

Both editors wish to acknowledge the expertise of each other and their knowledge of our field, their extensive network of contacts, and their ability to work closely together to ensure the success of this encyclopedia. Neither of them could have completed this project alone.

They acknowledge and thank the Taylor & Francis Group editors, Claire Miller and Rich O'Hanley, as well as Susan Lee, who passed away at the early stages of the preparation of this edition, and more recently, Alexandra Torres, who supported and kept the editors and authors on track over the course of the years of work on this edition of the encyclopedia.

The editors thank the authors who wrote and revised entries, and the huge number of reviewers who refereed the entries. Without their dedication, expertise, and willingness to share their knowledge with others, there would be no encyclopedia. They also wish to thank the Editorial Advisory Board for their advice, suggestions of topics and authors, their hours spent writing or reviewing for the final edition. They also wish to thank the previous editors, Marcia Bates and Mary Niles Maack, whose organization and structure for ELIS-3 provided an excellent blueprint for ELIS-4.

Physical Sciences and Mathematics Literatures and Their Users

Cecelia Brown

School of Library and Information Studies, University of Oklahoma, Norman, Oklahoma, U.S.A.

Abstract

The literatures of the physical sciences and mathematics are as diverse as the information wants and needs of their users while serving the common purpose of disseminating their research findings. The peer-reviewed journal is the hallmark of scholarly communication for physicists, astronomers, chemists, and mathematicians yet each discipline has its own unique information sharing practices. This entry discusses the information behavior of physical and mathematical scientists and the ways in which their literatures mesh with their distinctive research activities. Although physicists and astronomers were among the earliest adopters of electronic modes of scholarly communication, chemists and mathematicians have been slower to embrace digital information sharing. This entry therefore also considers the influence of electronic distribution of physical science and mathematical information on the ways in which their intended audiences access and manage the plethora of digital resources. Recent initiatives designed to facilitate access to the literatures of physics, astronomy, chemistry, and mathematics are also surveyed.

INTRODUCTION

Physical scientists study nonliving matter and energy through the lenses of the disciplines of physics, astronomy, and chemistry. Employing the scientific method, physical scientists develop concepts and theories to explain the physical world. Mathematicians are interested in numbers, quantities, and magnitudes and their relationships as well as the properties of space. Using methods involving logical reasoning and symbolic notation mathematicians investigate applied and theoretical problems in algebra, analysis, arithmetic, calculus, geometry, and trigonometry. The peer-reviewed journal is the hallmark of scholarly communication among both physical scientists and mathematicians; however, there are variations in the ways in which physicists, astronomers, chemists, and mathematicians access the information they want and need to support their research and creative activities. These differences in information behavior are reflected in the ways in which the different literatures of astronomy, physics, chemistry, and mathematics are organized, disseminated, accessed, and archived.

Beginning with a discussion of the traditional model of scientific communication, this entry describes the information behaviors of three groups of physical scientists: astronomers, physicists, and chemists, as well as the information behavior of mathematicians. Also considered are the ways in which the physical sciences and mathematics literatures mesh with their intended audience's information access and delivery preferences. Attention is given to the ways in which physical scientists and mathematicians handle the burgeoning body of information generated via high-output, cutting-edge scientific techniques plus their usage and acceptance of scholarly information that has not

only recently become accessible electronically but also that which is born digitally. This entry provides librarians and information scientists with an overview of the current understanding of the ways in which physical scientists and mathematicians access and use information to support their scholarly work. This understanding will enable the design and creation of products and services that facilitate, enhance, and improve the management, organization, and provision of information resources that not only meet, but also match, the specific information requirements and behaviors of physical scientists and mathematicians.

MODELS OF SCIENTIFIC COMMUNICATION

William Garvey and Belver Griffith discovered in the early 1970s through the observation of psychologists that scientists' information behavior is intimately tied to the ways in which they conduct their scientific work.^[1] Garvey and Griffith's model of scientific communication delineates the path scientific results travel from the laboratory to citations in the peer-reviewed journal literature. Along the way scientific results are disseminated locally at seminars and colloquia, followed by presentations at regional, national, and perhaps even international, scientific meetings. After vetting the results in these venues, the results may be deemed worthy for submission to a peer-reviewed scientific journal for publication consideration. Once a report of scientific findings has successfully traversed the gauntlet of peer review and become published, indexing and abstracting services catalog the article's bibliographic information to provide the scientific community with an entree to the results. Subsequent researchers whose projects are informed by the published reports then

cite the article in their scholarly publications thereby furthering the accessibility to the scientific results through reference linking. Running in tandem with Garvey and Griffith's model of scientific communication is an informal form of discourse described over 40 years ago by Price and Beaver as the "invisible college."^[2] Similar to the prototypical office water cooler, informal, yet highly valuable, communication among scientists takes place in the hallways of academia, at social gatherings during professional conferences, as well as over the telephone and through written correspondence. In contrast to formal scientific communication, which can be traced through the journal literature and via indexing and abstracting tools, informal scientific communication is difficult to track as it is not codified and archived even though its impact on scientific information behavior can be significant.

Moving forward in time to the beginning of the twenty-first century, Garvey and Griffith's model still holds true with the peer-reviewed journal remaining the coin of the realm for dissemination of scientific research findings. However, the advent of the Internet and the World Wide Web has impacted the ways in which physical scientists and mathematicians not only access, but also create and share, the results of their research endeavors. The creation of public and private online repositories of scientific data allows scientists and mathematicians to exchange information with a wide array of collaborators, as it is being generated, without having to first pass through the peer-review gauntlet. Electronic preprint servers and online journals deliver up to date scientific information to scientists' desktops around the clock. Online forums and electronic mail allow physical scientists to discuss issues of scientific importance with their colleagues without constraints of

borders, time zones, and languages. The model of electronic scientific communication proposed by Lancaster^[3] and revised by Hurd^[4] as presented in Fig. 1 incorporates these modes of electronic communication suggesting that the flow of scientific information will soon circumvent printed journals, indexes, and abstracting tools and will eventually be entirely digitized. Even though electronic communication facilitates information sharing and dissemination among physical scientists and mathematicians, the forecasted completely digital model of information flow has received varying degrees of acceptance by physicists, astronomers, chemists, and mathematicians.

THE LITERATURES AND THEIR USERS

A major task for all physical scientists and mathematicians is discovering, collecting, and reading articles about their area of research. Tenopir and colleagues found that time spent in reading by physicists, astronomers, and chemists, ranges from 144 to 198 hours per year.^[5] To access their literatures, physical scientists and mathematicians have at their disposal a myriad of indexing and abstracting services which employ an array of organizational schemes and offer a variety of access points. Providers include the American Association for Mathematics, a nonprofit professional society, as well as the scientific publishing powerhouse, Elsevier. Physical scientists and mathematicians have the option to access their literatures using not only sophisticated citation searching techniques through the Institute for Scientific Information's (ISI) *Science Citation Index* but also via simple, yet powerful, keyword searches

Fig. 1 Hurd's revised Garvey/Griffith model.

Source: From Hurd,^[4] on p. 22.

using Chemical Abstracts Service's *SciFinder*. The information yielded ranges from bibliographic data for monographs and journal articles to full-text page views and research related data. The wide variety of bibliographic services available gives physical scientists and mathematicians great latitude in finding tools that meet their information seeking preferences and needs. Of note in the scholarly communication cycle of physical scientists and mathematicians are the prestigious journals, *Science* and *Nature*, published by the American Association for the Advancement of Science and the Nature Publishing Group, respectively. Also worthy of mention is the *Proceedings of the National Academy of Sciences*, published by the National Academy of Sciences of the United States, a scientific and engineering honor society dedicated to furthering science and technology for the benefit of the general public. These interdisciplinary publications are highly sought after venues for publication of research findings for all physical scientists, as well as mathematicians, and are the cornerstone of any science information collection. Even though the ultimate goal is the publication of research results in a peer-reviewed journal; physicists, astronomers, chemists, and mathematicians exhibit different information behaviors that are tightly aligned with their field of study and also the characteristics of their literatures.

Physics

Physics is considered to be the most basic of the physical sciences as physicists ask fundamental questions about energy and the structure of matter and their interactions in the universe. Physicists study physical phenomena within systems as large as the Milky Way galaxy or as small as the subatomic quark. Approximately 20% of physics research involves collaboration between several scientists around the world using large equipment with substantial support from private and federal agencies. Often referred to as "Big Science," this is particularly the case for research in high-energy physics where it is not unusual for over 50 scientists from several universities and research institutions to author a single journal article. Notable for a high volume of research and publications are the Stanford Linear Accelerator Center and the Fermi National Accelerator Laboratory, which employ thousands of scientists and engage in worldwide collaboration with many more. The majority of physicists, however, work individually or within smaller groups in one of several physics subfields including chemical, condensed matter, and molecular physics where funding remains critical but the research is less equipment intensive. Regardless of the size of the project or group, or the topic of investigation, physicists strive to disseminate their results via peer-reviewed journals.

Two scientific societies, the American Institute of Physics (AIP) and the Britain-based Institute of

Physics (IOP), are responsible for publishing, indexing, abstracting, and archiving a significant fraction of the physics literature. The freely available *Scitation* from the AIP provides references to 1 million documents in scholarly journals, magazines, and conference proceedings from a range of scientific societies and technical publishers. Coverage is not limited to physics or the AIP and full-text is available to subscribers. Also accessible by subscribers from AIP is *Searchable Physics Information Notices (SPIN)*, which hosts more than 1.5 million article abstracts including publications indexed in *Scitation*. The AIP makes it possible for subscribers to search both *Scitation* and *SPIN* simultaneously for a comprehensive search of the physics literature. Additionally, the American Physical Society, a member of the AIP, has a free searchable Web interface for mining the contents of its suite of journals. The IOP similarly allows users to search their journals without charge plus users may freely download all papers published by the IOP for 30 days from the date of online publication. Physicists interested in issues related to engineering and technology make use of the Institution of Engineering and Technology's (IET) *Inspec* database. A new institution formed in 2006 by the joining together of the Institution of Electrical Engineers and the Institution of Incorporated Engineers, IET indexes and abstracts more than 3500 scientific and technical journals and 2000 conference proceedings, plus books, reports, and dissertations. The suite of IET journals is freely searchable via the *IET Digital Library*. Large, profit-generating publishing houses such as Springer, Elsevier, Taylor & Francis, and John Wiley & Sons also publish the research findings of physics and make the bibliographic information freely searchable via sophisticated Web interfaces; however, users must engage in licensing agreements to access full-text publications.

The commitment of physics scientific societies and publishers to make experimental results accessible online is reflected by the discipline's early adoption of electronic information dissemination. Physicists were among the first physical scientists to embrace electronic publication of their research findings with the IOP and AIP creating digital journal archives with searchable interfaces in the early 1990s. Perhaps the most significant indicator of acceptance of digital distribution of research findings by physicists is the extensive use of the online preprint server, *arXiv.org*. A preprint is the precursor to an article that is in the process of being submitted or has been submitted for publication consideration in a peer-reviewed journal. Physicists, particularly high-energy physicists, have been disseminating their research results via preprints for over four decades to facilitate large international collaborations, to avoid duplication of effort, and to bypass lengthy journal publication schedules.^[6] Before the widespread adoption of the Internet, the paper preprint was used to share physics research information; however, the electronic preprint, or eprint, has replaced this classic mode

of information exchange. The transition to eprints was a natural one for computer literate physicists who value the immediacy, efficiency, and simplicity of electronic communication. Developed by physicist Paul Ginsparg in 1991 for use by a group of 200 physicists at Los Alamos National Laboratory, *arXiv.org* has grown to be a repository of approximately 430,000 eprints and is connected to by approximately 450,000 visitors around the globe per day. Encompassing eight subfields of physics in addition to four areas of high-energy physics, *arXiv.org* also archives eprints in the areas of mathematics, computer science, quantitative biology, and statistics. Other eprint servers available for the high-energy physics community include *Stanford Public Information Retrieval System (SPIRES)* and the Central European Research Network's (CERN) document server. Physicists' acceptance of eprints in their scholarly communication cycle is indicated by the similar citation rate of eprints from *arXiv.org* and *SPIRES* to that of peer-reviewed journal articles.^[7]

Originally a purely physical science, physics has become interdisciplinary in nature with overlap in many areas including astronomy, computer science, mathematics, medicine, chemistry, biology, and engineering. As a result, physics research has both theoretical and practical arms with the research results being dispersed across the literature of several scientific disciplines. For example, physicists who partner with medical colleagues to develop new techniques for cancer detection using noninvasive scanners employing magnetic resonance imaging (MRI) techniques may find a medical journal to be the best outlet for their results. Although there are journals that concentrate on interdisciplinary issues in physics such as the IoP's *Physics in Medicine and Biology* and the AIP's *Journal of Chemical Physics*, physicists engaged in interdisciplinary research are nonetheless required to be cognizant of the need to search beyond the physics literature to inform their research activities. Helpful in this endeavor is the National Library of Medicine's (NLM) index to the biomedical journal literature, *Medline*, which is also known as *PubMed*. The terminology used to assign topic headings to the articles within *Medline* is available in NLM's *Medical Subject Headings (MeSH)* database. A MeSH search for the three main physics terms: physics, health physics, and nuclear physics also locates several subheadings such as radiation protection, biophysics, and rheology and retrieves over 150,000 articles. Databases available from ISI also facilitate interdisciplinary work in physics. Of specific utility is *Science Citation Index* which was conceived by Eugene Garfield in 1955 as a tool for searching forward in time from a known article to articles citing that article. A cited reference search in the online version, *Web of Knowledge*, for Albert Einstein's 1906 *Annalen Der Physik* publication about the theory of Brownian motion yields a list of more than 500 publications that cite the seminal work thereby highlighting not only the paper's importance to the field of physics but also

denoting other works that further inform the reader about the random movement of particles.

Astronomy

Perhaps the oldest of the physical sciences, the study of astronomy has classically involved the structure, relative positions, and motions of the bodies in the universe including the earth. More recently, astronomers have turned their attention to the physical properties of astronomical objects to gain an understanding of the development, composition, and evolution of galaxies and planetary systems. Similar to high-energy physicists, astronomers collect data using very large-scale equipment such as the earth bound Mauna Kea Telescope in Hawaii or the orbiting Hubble Space Telescope. Before 1957, astronomy was a small field, where both amateur and professional astronomers studied and recorded observations of the sky. The launch of Sputnik by the Soviet Union stimulated the United States to establish the National Aeronautics and Space Administration (NASA) in 1958 thus beginning the era of "Big Science" in astronomy.^[8]

Research in astronomy is highly data driven and technology dependent. Several scientists collaborate together on expensive, equipment-intensive projects like NASA's Mars Exploration Rover Mission while smaller groups and individuals purchase research time from observatories to collect information about the formation of black holes, the death of stars, and the rate of the universe's expansion. Whether the project involves several scientists or a single professor and their students, astronomers collect large volumes of data, often over prolonged time periods, which require extensive computing capability to house, organize, and maintain. The information amassed ranges from images and spectrographs to astrometric and photometric data all of which retain their value indefinitely thereby causing data preservation to be critical for the life of the project and beyond. Astronomers require access to not only research findings published in peer-reviewed journals but also to the original raw data. This access has classically been provided through astronomical catalogs that present data compiled from completed projects in a static print or CD-ROM format. Examples include Francis Wollaston's *A Specimen of a General Astronomical Catalogue* published in 1789 and the more recent *Second US Naval Observatory CCD [Charged Coupled Device] Astrogaph Catalog* published for the American Astronomical Society (AAS) by the AIP in 2003, the final volume of which is expected in 2009. The Internet now affords access to dynamic sets of data via several online repositories that rapidly provide highly specific information to support astronomers' research activities using sophisticated search interfaces. The spectrum of repositories is constantly changing and growing with foremost projects including *NASA/IPAC Infrared Processing and Analysis Extragalactic Database (NED)*, operated by the

California Institute of Technology's Jet Propulsion Laboratory, and *Set of Identifications, Measurements, and Bibliography for Astronomical Data* (SIMBAD), overseen by the Strasbourg Astronomical Data Center. Recently updated in March of 2007, *NED* provides spectral and photometry data for over 80,000 objects plus links to over 1 million journal and thesis abstracts. Equally impressive are *SIMBAD*'s current collection of over 3.5 million objects, 200,000 bibliographic references, and 5.5 million citations to objects in journal articles.

Recognizing the challenges of staying abreast with the highly dynamic nature, as well as the increasing magnitude, of online astronomy data repositories, nine astronomers at seven institutions across the globe merged their personal lists of online resources in 1994 to create *AstroWeb*. In addition to listing data resources, *AstroWeb* also links astronomers to astro-phy, the astrophysics archive of *arXiv.org*, and *ADS*, the Smithsonian/NASA Astrophysics Data System, which acts as a freely searchable portal to the astronomy and physics literature. Although subscriptions are needed to access most of the peer-reviewed content, when possible *ADS* provides a direct link to the *arXiv.org* eprint. Similar to physicists, astronomers appreciate the immediacy, ease of use, and free availability of eprints and are loyal users of and contributors to *arXiv.org* with 18.5% of submissions to the eprint server being to the astrophysical subject section. In addition to accessing the astronomy literature via *ADS* and *arXiv.org*, astronomers can also search the *Astronomisches Rechen-Institut Bibliographical Database (ARIBIB)*. A freely available online database, *ARIBIB* is based on the printed bibliography, *Astronomy and Astrophysics Abstracts*, however much of content in *ARIBIB* is also indexed in IET's *Inspec* database. The AIP's *Scitation* and ISI's *Web of Knowledge* are additional valuable resources for tapping the astronomy literature.

The limited number of astronomy-specific bibliographic databases is reflected in the narrow range of astronomy journals with the Royal Astronomical Society of Britain's *Monthly Notices of the Royal Astronomical Society* and the AAS's three publications: *Astronomical Journal*, *Astrophysical Journal*, and *Astrophysical Journal Letters*, being among the most highly read in the field. This small corpus of astronomy journals helped contribute to the ease with which the astronomy community adopted electronic publication of their scholarly works. The AAS, like their physics counterparts IOP and AIP, was a leader in electronic scholarly publication by offering their *Astrophysical Journal* online in the mid-1990s, with the online dissemination of their other publications following shortly thereafter. The small body of astronomy literature is enriched by its interweaving with that of physics. The tight relationship between the astronomy and physics communities is exemplified by AIP's publication of the journals *Astronomy Letters* and *Astronomy Reports* as well as EDP Science's, *Astronomy and Astrophysics*. Also

extending the astronomy literature is that of cosmology, the study of the universe as a whole, as illustrated by the research reports published in IOP's highly rated, *Journal of Cosmology and Astroparticle Physics*. In addition to physics and cosmology, astronomers are embracing additional disciplines such as paleontology, biology, and chemistry as they strive to understand the origins of life in the universe. The journal *Astrobiology*, launched in 2001 by Mary Ann Liebert Inc., exemplifies this trend by publishing articles about astropaleontology, bioastronomy, and cosmochemistry.

Chemistry

Chemistry is the physical science concerned with the properties, composition, and structure of matter and how it can be transformed from one substance to another. The subfields of chemistry include organic, inorganic, physical, analytical, and biological. Biochemistry, the chemistry of living things, has its own distinct, vast literature and biochemists possess unique information needs and information behaviors that differ from the other branches of chemistry. This entry emphasizes the information behavior and literatures of chemists who are considered to be physical scientists rather than that of biochemists. In all fields of chemistry, the literature is expanding at a swift pace with the American Chemical Society (ACS) currently publishing approximately 30,000 articles per year. As a result chemists download, view, and read far more journals than any other physical scientists.^[9,10] Chemists, who primarily work individually or in small groups with equipment needs ranging from basic balances and pipettes to more expensive ultracentrifuges and mass spectrophotometers, universally require immediate and thorough access to up-to-date research findings that are primarily presented in short articles containing explicit methodologies and graphical data displays.

Similar to the fields of physics and astronomy, the ACS began making their journal content available on their website to subscribers in the mid-1990s beginning with the *Journal of Physical Chemistry*. In the fall of 1997 all of the ACS journals became available from 1996 forward. Ultimately in 2002, the ACS Journal Archives made the entire suite of 35 journals containing over 750,000 articles available online from the first published issue and volume beginning in 1879. The ACS journals are among those most highly cited in the field of chemistry, particularly the multidisciplinary *Chemical Reviews*, *Accounts of Chemical Research*, and the *Journal of the American Chemical Society*. The ACS also publishes several journals in each subfield of chemistry including the important titles *Analytic Chemistry*, *Organic Letters*, *Chemistry of Materials*, and *Inorganic Chemistry*. The Royal Society of Chemistry (RSC), ACS's older European counterpart, publishes over 20 prestigious titles in a variety of areas of chemistry. The RSC online gateway allows subscribers to reach the

full-text of more than 240,000 articles published from 1841 to present. Titles range from the multidisciplinary *Chemical Society Reviews* and *Chemical Communications* to the discipline-specific *Journal of Materials Chemistry* and *Natural Product Reports*. Both societies offer a free Web-based search interface to gain bibliographic access to their journals; however, the primary database for comprehensive searching of the chemistry literature is *Chemical Abstracts*. Produced by Chemical Abstract Service (CAS), a division of the ACS, *Chemical Abstracts*, in addition to several other ACS databases, is searchable online via CAS's online portal, *SciFinder*. Even though *SciFinder* is expensive and access is complicated by firewalls and convoluted downloading procedures, *SciFinder* is nonetheless the premier search interface for accessing the chemical literature. Bibliographic information is not restricted to the publications of the ACS but rather strives to include all publishers of chemistry information from John Wiley & Sons and the Nature Publishing Group to the Indian Institute of Chemical Engineers and the Polish Academy of Science. Full-text is available to titles to which the user's institution subscribes. For individuals and institutions whose budget cannot afford the yearly subscription fee and/or who only need occasional access, the CAS databases are available for a per-search fee via ACS's online search service *STN* and ProQuest's *Dialog*.

A discussion of the products available from the 100-year-old CAS is critical in understanding the information behavior of chemists. Housed in Columbus, Ohio, CAS's 2000 employees index and abstract the extensive literature of chemistry. Access is provided to 9500 journals and patents from 1840 to the present in a manner that aligns with the way chemists work. The *SciFinder* interface offers access to more than 13 million chemical reactions through *CASREACT* as well as information about suppliers of commercially available chemicals via *CHEMCATS*. The information in *SciFinder* is accessible not only by simple keyword and author queries but also by chemical structure and molecular formula, the fundamental language of chemistry. Information can also be located using a CAS Registry number from the *CAS REGISTRY* database, which provides a unique numeric identifier for more than 31 million organic and inorganic substances. Originally a unique feature from CAS, the powerful ability to look for information using the standard CAS Registry number has recently met with competition from the National Institute of Health's (NIH) *PubChem*, a free online repository for storing records of small organic molecules. Although created for accessing biomedical resources, *PubChem* is remarkably similar to *CAS REGISTRY* in that it is based on a system of unique Chemical Identification Numbers (CIDs), which are housed in NIH's *ChemID* database. Information is available for over 380,000 chemical records, including 260,000 chemical structures, and is searchable using a wide range of options including CAS Registry number, molecular formula, and chemical

structure. The NIH considers the free *PubChem* to be directed toward a different audience than, and therefore is complementary to the subscription only *CAS REGISTRY*. Nonetheless, the ACS is concerned about the impact NIH's free service will have on their organization's endeavors. While NIH and CAS debate the issue, *CAS REGISTRY* and *PubChem* continue to thrive and provide chemists with a controlled vocabulary with which to identify chemical compounds and their properties thereby facilitating access to their literature.

To standardize and support worldwide chemical communication the scientific, nongovernmental International Union of Pure and Applied Chemistry (IUPAC) was formed in 1919 to create a common chemical language. The IUPAC is considered the world's authority on chemical nomenclature and terminology plus the standardized methodologies for collecting measurements, atomic weights, and several other forms of data. The IUPAC core series of four publications, commonly referred to as the Red, Blue, Green, and Gold Books, provide rules for the nomenclature of organic and inorganic compounds, lists of quantities, units and symbols in physical chemistry, and definitions of technical terms used in chemistry. Updated information is provided in the quarterly *Journal of Physical and Chemical Reference Data* which is published by the AIP for the National Institute of Standards and Technology (NIST). Although the journal is not a typical peer-reviewed publication of original experimental results, it is a critical reference source for chemists as well as physicists. Two additional indispensable tools for chemists are the *Beilstein Handbook of Organic Chemistry* and its inorganic counterpart, *Gmelin*. First published as monographic series, the two resources are now available together in the online product, *Crossfire*, through which chemists can search structures, properties, and literature references for organic, inorganic, and organometallic compounds using Elsevier's MDL Crossfire Commander client software. Similarly, Springer's *Landolt-Börnstein* series of data handbooks provides chemists with mechanical, electrical, and thermodynamic property data for inorganic and organic substances. A freely searchable online interface allows chemists to use molecular and elemental formulae, CAS Registry numbers, or chemical names to find the volume within the *Landolt-Börnstein* series in which the desired information can be found.

In addition to requiring access to data about chemical compounds and to the journal literature, chemists also need the ability to search national and international patent repositories. This is especially critical for chemists working in the pharmaceutical, petrochemical, and agricultural industries, as well those in academia, who must be knowledgeable of current developments to retain a competitive edge. The United States Patent and Trademark Office's free online database indexes patents issued in the United States since 1790. A comprehensive and global patent search is available through CAS's *SciFinder* which allows

chemists to simultaneously look for patents from 50 international patent-issuing authorities while also exploring the journal literature. Additional access to the patent literature is available through Thomson Scientific's *Derwent World Patents Index* (DWPI) which provides value-added expert analysis including a "Novelty" paragraph outlining the less than obvious technology improvements over previous patents as well as a "Technology Focus" abstract highlighting technological perspectives of the invention. Access to DWPI is available on a per-use or subscription basis via several platforms including ProQuest's Dialog and *Westlaw*, and CAS's *STN*. It is also possible to search and discover patents issued around the world using ISI's *Web of Knowledge* in tandem with a search for journal articles.

In contrast to physicists and astronomers, chemists do not wholeheartedly embrace eprints as part of their scholarly communication. The *Chemistry Preprint Server* (CPS) produced by Elsevier was active from only 2000 to 2004 even though chemists believed the eprints posted to be of high quality and appreciated the forum provided by the CPS for open discussion of current chemical research.^[11] Despite the positive reception of the CPS, chemists' concern about the lack of peer review and the uncertain permanence of eprint storage, coupled with the refusal of editors of the top chemistry journals to subsequently publish papers previously posted on the server, the CPS was destined to fail. The chemistry related holdings in *arXiv.org* are limited to a small microcosm of eprints in the field of chemical physics. Even though chemists are reluctant to capitalize on free eprint distribution of their work, the ACS has a long tradition of making research-related data available to its readers, first as microfilm and now as free electronic files in the ACS *Electronic Supporting Information* archive. Similarly, the RSC's *Electronic Supporting Information* (ESI) service allows authors to deposit repetitive experimental details and large data sets including color diagrams, three-dimensional molecular models, and movies in this free repository. This practice of making research-related data openly accessible enhances chemists' scholarly communication by giving readers free access to potentially useful information while saving valuable journal page space.

Mathematics

Mathematicians study magnitude, quantity, and numbers and their relationships, as well as the properties of space, using logical reasoning methods and symbolic notation. Branches of mathematics include geometry, algebra, analysis, and applied mathematics. It is contended that mathematics is a philosophy rather than a science as mathematics involves the rational investigation of questions about existence and knowledge rather than being a process for evaluating empirical knowledge. In practice, though, mathematics is a combination of philosophy and science

depending on the nature of the problem being studied. Problems in mathematics can be purely theoretical in nature where patterns or relationships are studied for the knowledge yielded or they can be highly practical wherein the patterns and relationships are used to develop solutions for traffic flow issues or to create a data categorization scheme. Similar to astronomy information, information in the mathematical sciences retains its relevance for many decades as classical techniques and theories are frequently utilized for finding solutions to modern day problems. As a result the information needs of mathematicians range from historical theorems to cutting-edge computer modeling techniques, which they acquire by browsing information published in both journals and monographs. A very unique aspect of mathematics is that it is a support discipline for virtually all other sciences including the social sciences wherein phenomena can be described, or problems solved, using mathematical formulae or theories.

Mathematics research is similar to that in chemistry as mathematicians tend to work individually or in small groups. However, despite their solitary work style, mathematicians highly value attendance at conferences and personal discussions with colleagues to develop and augment their research ideas and processes.^[12] This is supported by the range of mathematical societies that hold conferences, fund research in mathematics, and publish mathematics journals. The American Mathematical Society (AMS), the premier mathematics society in the United States, lists 110 national and international mathematics societies, associations, and groups on their Web site. The list includes the Estonian and Hellenic Mathematical Societies as well as the Clay Mathematics Institute in Cambridge, Massachusetts and the International Society of Dynamic Games in Finland. This breadth and diversity of mathematics-related organizations are evidences of the great importance of social networking in the daily work of mathematicians.

As is the case of the physical scientists discussed above, the peer-reviewed journal is the hallmark of dissemination of research information among mathematicians. The AMS publishes their suite of journals in a combination of print and electronic formats and includes the highly rated *Journal of the American Mathematical Society*, an outlet for articles about both pure and applied mathematics. Princeton University's top ranked *Annals of Mathematics* publishes reports of pure mathematical research while a wide array of field-specific titles such as *Geometry & Topology*, the *Journal of Differential Equations*, and the *Journal of Functional Analysis* provide researchers studying highly specific problems a venue to share their findings. Applied mathematics researchers find a prime outlet in the titles published by the Society for Industrial and Applied Mathematics (SIAM) including the very specific *SIAM Journal on Matrix Analysis and Application* and the more general *SIAM Review*. Most mathematics journals are available in both print and electronic

formats with some exceptions such as the AMS's *Conformal Geometry and Dynamics* and *Representation Theory*, which are both published purely electronically. In an effort to make global research more accessible to its members, the AMS has a long-standing practice of translating mathematics journals into English from other languages especially Russian and Japanese. Currently four translation journals are fully searchable on the AMS online search interface: *St. Petersburg Mathematics Journal*, *Sugaku Expositions*, *Theory of Probability and Mathematical Statistics*, and the *Transactions of the Moscow Mathematical Society*.

A unique aspect of mathematics scholarly communication is the key role played by monographs and monographic series. For example, Springer's *Graduate Texts in Mathematics* series is comprised of over 240 titles providing advanced-level introductions to research in a wide variety of topics including group theory, complex analysis, and Lie groups. The Oxford University Press publishes a similar series titled *Oxford Graduate Texts in Mathematics*, albeit on a smaller scale. Also of note is Springer's *Lecture Notes in Mathematics* series, published since 1964, which presents lectures about new fields of mathematics as well as fresh perspectives on classical mathematics. The expository presentation style of the *Graduate Texts* and *Lecture Notes* is echoed in the AMS's *Bulletin* and *Notices* journals. The *Bulletin* publishes peer-reviewed articles about current research topics written for the nonexpert while the *Notices* serves as a current awareness vehicle for mathematicians while including explanatory articles about current developments in mathematics research. Additionally, the AMS publishes 17 monographic series ranging from a sequence of research volumes generated from the Fields Institute for Research in Mathematical Sciences to *What's Happening in the Mathematical Sciences*, a series devoted to describing cutting-edge research in modern pure and applied mathematics at a level accessible to those with a high school mathematics education. Furthering the worldwide scholarly exchange in mathematics are the AMS's series of research and expository monographs that have been translated from Japanese, French, and Russian into English. One example is the series of *SMF/AMS Texts and Monographs* which is copublished with the Société Mathématique de France (SMF) and includes translations of the well-regarded series, *Astérisque*.

Mathematicians use two very distinctive tools to gain access to their literature: *Zentralblatt MATH (Zbl)* and *Mathematical Reviews (MR)*, which not only index and abstract, but also review, the literature of mathematics. The reviewing feature is further illustrative of the high value mathematicians place on discourse with their colleagues around the world. Although the reviews are not fully equivalent to face-to-face, real-time interaction, they do provide a forum for assessing and discussing a work, a feature that sets these apart from traditional bibliographic

tools. Originally titled *Zentralblatt für Mathematik (Zbl)*, became available in 1931 and is edited by the European Mathematical Society, the Heidelberger Academy of Sciences, and Fachinformationszentrum or Specialized Information Center (FIZ) Karlsruhe. Published by Springer-Verlag, *Zbl*'s coverage extends from 1868 to the present with some full-text availability. The reviews in *Zbl* are primarily in English, with some French and Russian content, by approximately 5000 scientists who analyze over 2000 journals, conference proceedings, and monographs per year. Similarly, AMS's *MR* provides mathematicians with bibliographic and selected full-text access to the mathematical sciences literature that is augmented by more than 60,000 new expert reviews each year. Reaching back to 1864, the online equivalent of *MR*, *MathSciNet*, holds 2 million items with direct links to over 700,000 articles. Since 1991, the citations in both *Zbl* and *MR* have been organized according to the *Mathematics Subject Classification (MSC)* which was updated in 2000 in a collaborative effort between the editors of *Zbl* and *MR*. The classification scheme was devised to facilitate access to the mathematics literature and employs two-, three-, and five-digit classification codes that correspond to a discipline of mathematics. For example, the *MSC* code for partial differential equations is 35 while the code 35B can be used to find information about qualitative properties of solutions. Even greater specificity can be gained by using the code 35B40 to locate information about the asymptotic behavior of solutions. The search interfaces of both *Zbl* and *MathSciNet* allow users to search for information using the code that corresponds to their area of interest. Also organized according to the *MSC* is AMS's *Current Mathematical Publications (CPS)*, which serves as an index of forthcoming mathematics publications. Published in print every 3 weeks and updated daily in *MR*, *CPS* is compiled by the editors of *MR*, and is searchable online via *MathSciNet*.

Although mathematicians are beginning to embrace electronic access to their literature, they continue to appreciate the browsing capability they believe to be distinctively afforded by printed information.^[13] The browsing behavior of mathematicians is similar to humanities scholars in that both groups look for connections between wide ranging information sources that they can apply to the problems they are currently studying. Another complaint voiced by mathematicians about purely electronic access is the maintenance of the archive in perpetuity.^[12] To help resolve this issue, as well as that of the ever-increasing issue of inadequate library shelf space, the non-profit organization, *JSTOR*, is committed to creating and maintaining a stable archive of full-text scholarly journals, including 54 mathematics titles. The page images in *JSTOR* have been scanned to retain their original format and have been found to be a reasonable alternative to print journals for some mathematicians.^[13] Titles available via *JSTOR* include publications from both AMS and SIAM as

well as Springer and the National Council of Teachers of Mathematics. Although mathematicians find an electronic-only environment hampers their ability to browse the literature, they are the fastest growing group of authors submitting their research reports to *arXiv.org*'s mathematics archive. More than 1000 new submissions were posted to *arXiv.org*'s mathematics archive per month in 2008, surpassing the rate of 750 per month submitted to the high-energy physics archive, traditionally the most active archive of *arXiv.org*. The mathematics archive of *arXiv.org* contains eprints from 1991 to the present that are organized into 32 categories including logics, spectral theory, and combinatorics. The growing submission rate to the mathematics eprint archive, plus the availability of several other mathematics eprint repositories from institutes and universities worldwide, including the Mathematics Sciences Research Institute in Berkeley, California, Florida State University, and Hokkaido University, indicates an increasing acceptance of eprints by mathematicians. To date, however, the role of eprints in the scholarly communication of mathematics remains to be fully investigated.

OPENLY ACCESSIBLE PHYSICAL SCIENCES AND MATHEMATICS LITERATURES

The information behavior of physicists, astronomers, chemists, and mathematicians is deeply rooted in the way in which they conduct their scholarly work. Although the peer-reviewed journal model is the highly sought after end product, new formats and modes of information flow in the physical sciences and mathematics are quickly emerging in response to the desire for electronically delivered information. The ability to freely access scholarly information online allows scientists to expand and enrich their traditional modes of scholarly communication while helping to combat the ever rising cost of acquiring scholarly scientific journals. For example, to temper the high cost of scientific journals, the Association of Research Libraries formed the Scholarly Publishing and Academic Resources Coalition (SPARC), in 1998. Fuelled by the belief that inordinately high-scientific journal costs restrict the scientific community's ability to access, share, and use scholarly information, SPARC has forged partnerships with over 220 academic and research libraries to support promotion of and access to quality journals free of charge or for a nominal cost. In their commitment to reducing subscription prices SPARC publishes titles such as the affordably priced, yet peer-reviewed *Geometry & Topology* and the all-electronic, freely available *New Journal of Physics*, as alternatives to similar, yet much higher priced, titles distributed by the for-profit sector. Further reducing price barriers to physical science and mathematics scholarly information is the *Directory of Open Access Journals* (DOAJ). Supported in part by SPARC and the Open

Society Institute, the DOAJ is additionally funded and maintained by Lund University Libraries and provides access to peer-reviewed or editorially controlled journals. Currently 15 astronomy, 52 physics, 87 chemistry, and 132 mathematics titles are available at no cost through the DOAJ portal. HighWire Press, a division of Stanford University Libraries, is another leader in providing unfettered access to the scientific literature. Beginning with the *Journal of Biological Chemistry* in 1995, HighWire Press works with scholarly societies, university presses, and publishers to create a fully searchable, online collection of the research literature. Although the focus is on the life sciences, physical scientists and mathematicians will find access to the full-text of several prestigious titles including *Science* and the *Proceedings of the National Academy of Sciences*, and the *Proceedings of the London Mathematical Society* via HighWire Press's easy to use search interface.

Although the efforts of SPARC, DOAJ, and HighWire Press are making great strides in ensuring continued access to critical research information in the face of rising subscription costs and shrinking library budgets, physical scientists and mathematicians still require access to information beyond the reach of these progressive services. Consequently, several institutions, including the University of Wisconsin at Madison and Trinity University, are experimenting with a pay-per-view model where scientists request the articles they wish to read on a per-article basis rather than acquiring a subscription to the complete journal. The direct desktop delivery of articles as PDFs (Portable Document Formats) complete with legible diagrams, clear scientific notations, and color images provided by the pay-per-view model aligns well with physical scientists' and mathematicians' information needs and desires. Of concern with this mode of delivery is the maintenance and storage of the downloaded article, as these functions now become the burden of the user rather than the library or information center. Additional complications include the user's rights to share the article with their colleagues and to archive the article for an extended time. The pay-per-view option is available through several providers including HighWire Press, Elsevier, and Ingenta.

To simplify sharing of science information, Science Commons, a branch of the nonprofit Creative Commons, began establishing standardized licenses in early 2004 through which scientists can enter into agreements to share their research results. Two large open access publishers, the Public Library of Science (PLOS) and BioMed Central have adopted the "some rights reserved" licensing advocated by Science Commons. In the spirit of Science Commons, college and universities throughout the world are establishing their own online repositories of research related materials produced by their faculty and researchers. An excellent example is *Purdue e-Scholar*, a digital repository of e-books, papers, reports, dissertations, journal articles, research data sets, and data files by Purdue

authors and researchers. Also of note is OhioLINK'S *Digital Resource Commons* which is committed to managing and preserving educational and research materials such as preprints, working papers, and dissertations from OhioLINK members and other Ohio institutions. On a national scale is the National Science Foundation's (NSF) National Science Digital Library (NSDL) which was created in 2000 to act as a dynamic repository of high-quality resources to support teaching and learning at all levels of science, technology, engineering, and mathematics education. Access to the free, well-organized resources are intended primarily to support science education; however, the research articles and data sets available from the NSDL are also of relevance to physical scientists and mathematicians. Furthering capitalizing on the Internet to facilitate and enhance the dissemination of scientific information is *SciVee*, an online multimedia repository where scientists can augment the content of their published works with narration, slides, and videos. Although still in its infancy, *SciVee*, the result of a partnership between the PLoS, the NSF, and the San Diego Supercomputer Center (SDSC), is contributing to the shift in scientific information dissemination from a one-dimensional article model to a multifaceted, interactive platform.

The rich and powerful online tools and services developed over the past decade are a boon to the scholarly communication of physical scientists and mathematicians, however, as their magnitudes and numbers intensify, the task of information seeking becomes highly complex. In 2000, several leading publishers of scholarly information including AIP, the Nature Publishing Group, Wiley, and Elsevier jointly formed the nonprofit, independent organization, Publishers International Linking Association, Inc. to promote the development and cooperative use of new and innovative technologies that speed and facilitate scholarly research. The result of the union is *CrossRef*, a collaborative reference linking service that helps users find additional articles of interest. Facilitated by Digital Object Identifiers (DOI), which are assigned to an article by participating publishers, *CrossRef* acts as a digital citation-linking network where, by clicking on a reference in an article, researchers are instantly directed to the cited article. Although *CrossRef* does not provide full-text access, it provides bibliographic information for millions of articles in journals of interest to physical scientists and mathematicians ranging from RSC's *PhysChemComm* to Elsevier's *Topology and its Applications* and IOP's *Chinese Journal of Astronomy and Astrophysics*. Elsevier is further working to facilitate the task of online searching across disparate scholarly resources with their science specific search engine, *Scirus*. The freely available service allows users to search over 415 million science-specific Web sites for scientific data, technical reports, peer-reviewed articles, patents, and eprints from providers like IoP, SIAM, and NASA. Perhaps the most promising and exciting new technology for managing digitalized

scientific resources is the *Google Scholar* library links program. The program, currently a beta service from the extremely popular search engine *Google*, allows libraries to link their holdings to *Google Scholar* thereby making it possible for scientists to mine the resources their institution has licensed using a single entryway. Scientists at universities including Northwestern, MIT, and Emory are able to use the familiar and straightforward *Google* interface to search their libraries' holdings and directly connect to full-text articles to which their institution subscribes, regardless of provider.

Although the reception and use of these forward thinking services by physicists, astronomers, chemists, and mathematicians remains to be fully elucidated, innovative programs like *SciVee*, *CrossRef*, and *Google Scholar* library links have great potential to facilitate the task of information seeking as digital access becomes the norm for scientific discourse. Regardless of format, delivery of scientific information in a mode physical scientists and mathematicians will utilize is critical to promoting and supporting innovation and progress in the physical sciences and mathematics. Physicists, astronomers, chemists, and mathematicians depend upon library and information centers to provide fast, comprehensive, and persistent access to information to support their research and creative activities. This has traditionally been the role of librarians and information scientists since the first libraries emerged 5000 years ago and remains the cornerstone of service in the emerging digital era. Continued awareness of the information behaviors and preferences of physical scientists and mathematicians is key to enabling the efficient and effective access to information products and services that scientists can rely on for the foreseeable future.

Piracy in Digital Media

Stephanie Walker

Brooklyn College, City University of New York, Brooklyn, New York, U.S.A.

Abstract

Piracy of digital media refers to the unauthorized copying, usage, and sale or distribution of copyrighted materials in digital form, excluding materials which have been created or are distributed either specifically as fully “open access” materials, or those which have been licensed under some form of “open access” license (such as, for example, that offered by Creative Commons—see <http://creativecommons.org/>). These materials may include software, audio files, music, video files, movies or TV shows (in their entirety or in part), or electronic versions of books, journal articles, or databases. The term “piracy” itself remains somewhat controversial, as it carries a pejorative connotation, and not all copying for which authorization is not specifically obtained constitutes any form of theft; many forms of copying are legal, including copying of fully open access materials or materials licensed under Creative Commons or similar organizations. Also, there are ongoing and long-standing debates on what constitutes “fair use”; however, these issues are complex and are, in many cases, still before the courts and the legislators. However, for simplicity’s sake, we will use the term “piracy,” as described above, with the noted exceptions, throughout this entry.

Piracy can be accomplished through a variety of means, including copying materials from one medium to another, e-mailing zipped copies of files, downloading materials from servers, and many more elaborate schemes. Piracy is a global phenomenon, which costs software producers, recording artists, movie and TV production companies, publishers, and others considerable revenue; the exact amounts are near impossible to determine and frequently under dispute. Legislation governing copyright and technology has tended to lag behind the pace of technological developments, and much newer legislation is controversial. There have been numerous lawsuits against companies and individuals purportedly engaged in piracy; individual companies and artists have launched such lawsuits, as have the Recording Industry Association of America (RIAA), the Motion Picture Association of America (MPAA), and various other organizations. However, many of these cases are in process or pending, and the legal issues remain unclear. The situation is similar in many other countries as well, and there are great variances in copyright law, laws governing Internet Service Providers (ISPs), filtering, and other issues that affect piracy matters. Technological solutions designed to halt or limit piracy have proven generally unworkable, and legislative issues are thorny and remain unclear in many ways.

INTRODUCTION

Piracy, when used in discussions of digital media, refers to the unauthorized copying, usage, and often sale or distribution of copyrighted materials (or materials for which some party has other intellectual property rights) in digital

form, excluding materials which have been created or are distributed either specifically as fully “open access” materials, or those which have been licensed under some form of “open access” license (such as, for example, that offered by Creative Commons—see <http://creativecommons.org/>). Also excluded are materials or portions of materials deemed to have been utilized under “fair use” provisions of copyright law (though “fair use” is, in the digital world, sometimes a disputed concept). A full discussion of “fair use” is beyond the scope of this entry; the interested reader is referred to Section 107 of the U.S. Copyright Act (title 17, U.S. code, online at <http://www.copyright.gov/title17/92chap1.html#107>), or to a discussion of fair use on the Web site of the U.S. Copyright Office, at <http://www.copyright.gov/fls/fl102.html>, and the topic has been discussed at length in legal, technical, and library literature.

Any discussion of piracy in digital media must necessarily encompass several major categories of digital media. There are common issues in discussing piracy across various types of digital media, but there are also specific considerations for various categories of media. Media and issues are outlined briefly here, but will be discussed in greater detail in the following section. Major types of digital media for which piracy is an issue include software (including various business applications), audio files/music, and video-based materials, including movies and television shows. Publishers who have ventured into e-books also have concerns about piracy. Indeed, digital intellectual property of any kind, from e-books to online lectures and classes to full-length creative works such as music albums or movies, is vulnerable to piracy. Piracy can be accomplished through a variety of means, from

simple copying of material to a portable media device such as a “flash” drive or CD to much more elaborate schemes. Piracy is a global phenomenon; where there are computers, Internet access, and digital materials, there is piracy at some level, though its prevalence varies greatly from one country to another. There are a number of factors that have been identified or posited as contributing to the likelihood of piracy being widespread, including economic factors, cultural factors, and more, along with factors which inhibit widespread piracy. Piracy of digital media can cause economic harm to producers and inhibit development of new software or artistic creations. However, digital hosting, sharing, or transmission of files can also provide a means by which lesser known or previously unknown content creators can gain exposure for their work, and potentially attract future sales. Some well-known musicians (including highly popular bands such as Radiohead, Oasis, and Nine Inch Nails, to mention just a few) have also utilized digital sharing of files or offered portions of their work at low or reduced prices or even at no cost, or have offered to allow users to pay what they wish. There are strong arguments that such sharing increases music fan bases and in some cases frees musicians from restrictive contract agreements.^[1] However, as has also been extensively reported in the media, major associations for the software, music, movie, and publishing industries have been taking aggressive (and frequently controversial) legal action to fight back against piracy.

PIRACY OVERVIEW: MEANS, PREVALENCE, AND COSTS

Software

Software can be quite vulnerable to piracy. Common business productivity software, especially, is often purchased by a single person, who then shares his one legal copy with friends, family, or colleagues.^[2] There are also numerous sites where unlicensed or illegally copied software is available for free or greatly reduced costs, either by downloading or by placing an order for a copy which is then delivered or sent to the user upon receipt of payment. In some countries, the rates of software piracy exceed 90%—meaning that for every 100 copies of software, only 10 (or fewer) have been legally purchased and installed (see below). The rest are illegal copies, sometimes known as warez.^[3] This affects software publishers’ revenues, and many publishers claim this leaves a lower level of funds available for investment and research in new or updated software applications. As long ago as the year 2000, Ram D. Gopal and G. Lawrence Sanders (who have written extensively on piracy-related issues) provided some specific and surprising details on the widespread and dramatic problems associated with software piracy.

They reported that as early as 1997, the Software Publishers Association estimated that losses due to piracy for business application software in the United States alone reached \$2.8 billion, and that worldwide, the revenue losses were estimated at \$11.4 billion, and in some countries, including Kuwait, Pakistan, Indonesia, Bulgaria, China, Turkey, Egypt, Bolivia, and El Salvador, the rate of piracy was estimated to approach or exceed 90%.^[2] Furthermore, because of a number of unique characteristics, software and other digital goods are particularly vulnerable to piracy: it is expensive to produce the first copy, but inexpensive to reproduce and distribute additional copies, and it is easy to share without impacting the value of the original product. “These idiosyncratic traits of software and related digital products,” they write,

have facilitated their illegal distribution worldwide. Several countries in the world are referred to as “one-legitimate-copy” countries, where one legal copy of a software package is sufficient to meet the demands of an entire nation. The advent of the Internet has amplified the problem. There are numerous warez (colloquial reference to pirated and cracked software) Web sites that permit customers to select from a menu of pirated software up to the 650 MB capacity of a CD. For around \$30–\$60, payable via credit card, the warez vendor will burn the CD and deliver it to the customer’s doorstep.^[3]

In the intervening years, there have been some changes in copyright law and there have been efforts by the U.S. government and by professional and business organizations to persuade other countries to take measures to lessen piracy rates, but they have met with mixed success, and in some cases with none. (It should also be noted that the Software Publishers Association merged with the Information Industry Association to become the SIIA—the Software and Information Industry Association.) “Many countries, particularly those without a viable local software industry, find it counterproductive to thwart piracy,” Gopal and Sanders argue.

While the threats of trade sanctions have arm-twisted many countries to enact copyright laws, they are rarely enforced. ... China, for example, has recently cranked up raids against CD factories that manufacture bootlegged copies of software and confiscated the CD presses (each worth as much as \$1 million). The suspicion, however, is these presses are put back into service in government-owned factories to manufacture CDs containing pirated software.^[4]

Meanwhile, the costs of piracy continue to rise. In 2006, the Business Software Alliance (BSA) estimated total costs of software piracy worldwide at \$40 billion, and reported that piracy rates have discouraged investment by software producers in some countries, such as the Philippines, where the BSA reports a piracy rate of 71% since

2004.^[5] However, in the same article, representatives of such major software publishers as Symantec, Alcatel-Lucent, and Adobe Systems are quoted as providing statements to the effect that piracy is a concern, but does not determine strategic direction and is not the primary concern, and that they have made various adaptations to fight piracy and continue to do so.^[5] Doubtless, piracy has an effect on revenue and on product distribution and development strategies; how much of an effect seems difficult to determine, and dependent on sources and methods.

Audio Files/Music

Piracy of audio files (especially music) is probably the best known area of digital piracy, due to heavy publicity surrounding court cases and activities by the RIAA and various music companies directed at stopping piracy, and due to statements by many artists on both sides of the file-sharing issues. The issues of pirated music, the services and tools which facilitate music file sharing and downloading, and the industry and legislative responses to such activities, have been widely reported in newspapers, magazines, and professional journals. Certainly not all shared music is pirated music; as aforementioned, many musicians support file-sharing or make portions of their music available for free or at reduced costs via various methods. As well, many users remember the days in the 1970s when the music industry claimed vociferously that home taping was killing music, and tried to discourage people from taping songs from the radio or sharing a homemade mixed cassette tape with a friend. It didn't work, and in reality, music sales grew. "Before the advent of home taping," writes Peter Martin, Economics Editor of the *Canberra Times*,

Americans bought around 2.5 long-playing records a year. After two decades of home taping, they were buying 4.5 recorded cassettes and LPs a year. Stan Liebowitz, a Professor of Economics at the University of Texas, argues forcefully that the explosion in recorded music sales wasn't accidental. It was caused by the introduction of the cassette. Before then, music listening was limited to one room in each house—the one with the record player. The advent of the cassette made it possible to listen in the car, while jogging, in the garden, practically anywhere.^[6]

Today, one commonly hears stories about the decline of the recorded music industry.

In a 2007 *Washington Post* article, Frank Ahrens reported that

The music industry experienced the greatest one-year loss in sales of compact discs last year, and rising revenue from songs and albums bought on the Internet failed to offset the consumer flight from CDs. Revenue from CD sales was down 13 percent last year compared with 2005, the

Recording Industry Association of America reported yesterday. The drop-off exceeds that of any year during the Napster era of 2001 to 2004, when the file-sharing service and its descendants—such as Kazaa and Grokster—allowed users to download music for free. Meanwhile, online sales of singles from services such as Apple's iTunes were up 60 percent last year. However, because online sales remain a small percentage of all music sales, the industry's total revenue—for tangible and online products—was down 6.2 percent compared with 2005, the RIAA reported. . . . The music industry has blamed piracy for the dive in CD sales and began suing downloaders and the file-sharing services in retaliation in 2003.^[7]

A lengthier discussion of legislative responses is included later in this entry; however, it is worth noting at this point that on December 22, 2008, an Associated Press report confirmed that the RIAA

. . . has abandoned its policy of suing people for sharing songs protected by copyright and will work with Internet Service Providers (ISPs) to cut abusers' access if they ignore repeated warnings. The move ends a controversial program that saw the RIAA sue about 35,000 people since 2003 for swapping songs online. Because of high legal costs for defenders, virtually all of those hit with lawsuits settled, on average for around \$3,500. The RIAA's legal costs, in the meantime, exceeded the settlement money it brought in.

This applies to individuals only; there is no current indication that organizations will no longer be sued.^[8]

Yet even in claims that music sales are being "destroyed" by illegal downloading, there appears to be conflicting information. Again in the *Canberra Times*, in response to a request by the Australian Recording Industry Association to have the Minister of Communications enact a "three strikes and you're out" law which would ultimately allow users to be cut off from Internet access if they were caught three times illegally downloading material, Peter Martin reported that according to the Australian Recording Industry Association's own sales figures, in 1982, sales of recorded music were at the level of 29 million units, and have risen steadily; now, ". . . after the most recent five years of sustained CD-burning, intensive file swapping, the introduction of the iPod, wringing by the industry, we bought 99 million—easily an all-time record and an impressive jump of 23 per cent on the year before."^[6] This includes not only 44 million units of physical CDs sold in that year, but also sales of new formats for music, including ring tones, digital albums, single tracks, music videos, and more. "The industry," Martin argues,

will argue that it would be selling even more if it wasn't for illegal downloading. It's hard to prove. Certainly it would be selling less if it turned back the clock to before

illegal downloads began. And it is highly likely that illegal downloads stimulate sales. That used to be the function of CD-singles—loss-making samplers that would introduce consumers to new music and new bands. CD singles are all-but extinct. At the start of the decade the industry sold 12 million. It now sells just 2.5 million, having ceded the promotional business to the file sharing sites it claims to hate. Without those sites we would be exposed to a lot less new music and we might buy less. . . . In the face of zero evidence that illegal downloads are hurting music sales or drying up the supply of music, the industry wants the Minister for Communications to empower our ISPs cut us off from the web if it finds we have been downloading something it does not want us to.^[6]

Again, we find conflicting reports from various sources on the effects which downloading (whether illegal or not) is having on the music industry, and thus on the effects of piracy on digital music.

However—to return to basics, including procedures and methods, and a brief history of music downloading—how precisely are music files shared? Music files are widely shared in many ways, including peer-to-peer networks which allow users to permit access a portion of their computer; networks and services which host files and allow for storage on their site; file-sharing services which allow users to post a file and notify a friend that the file is there for them to retrieve; or simple e-mailing of compressed files.

In some peer-to-peer networks, one must apply for “membership” to the network. One example of a way to apply for membership might be to offer to share rare or desirable files; this was the model followed by a service known as Hotline. If your application is approved by the site organizers, then you can access other files available through the network. But you must upload the promised files, or permit network members to access a secured portion of a server where these files are located. Many files shared via such services were not illegally obtained or even copyright protected, and often materials were not uploaded to servers owned by the company, but naturally, copyrighted and pirated materials were sometimes available. However, the idea was that responsibility for copyright clearance would fall upon the users, as would liability for infringements. There were many such networks and services that facilitated file sharing, and many persist. Such services, however, never obtained the notoriety or popularity of later incarnations such as Napster.

Napster was started by Shawn Fanning, a young programmer and student at Northeastern University in Boston, MA, and ultimately released by Fanning and two friends, Jordan Ritter and Sean Parker. It was the first well-known (and wildly popular) peer-to-peer file-sharing service. The service was unveiled broadly in 1998. The difference between Napster and many earlier peer-to-peer sites was that users could upload music files to,

and download music files from, Napster itself, and the files were hosted on Napster servers. Users liked the cost (free), the ease of use, and the ability to download only songs they liked and create their own compilation CDs. Musicians could also post their own songs on Napster, and many did so in hopes of stimulating growth in their audience; it was a means of marketing their material and hopefully stimulating radio play and future sales. However, music industry players soon launched multiple lawsuits against Napster, claiming that Napster’s actions and services were illegal and facilitated theft; certainly, some of the material that users posted on Napster was copyrighted, non-open access material, for which permission to post had not been sought. The RIAA launched a lawsuit against Napster in December 1999. The band Metallica was infuriated that some of their work was circulating on Napster, and shortly thereafter being played on radio stations, even before it was even released for commercial sale. Dr. Dre, Madonna, and other artists soon followed suit. In 2000, A & M Records sued Napster under the Digital Millennium Copyright Act (DMCA). The plaintiff’s lawyers contended that Napster’s users were directly infringing copyright, that Napster was liable for contributory copyright infringement, and that Napster was liable for vicarious copyright infringement.^[9]

Napster argued that it was not liable for users’ breaches of copyright, and that it could be used for many noninfringing purposes as well. Many users also contended that file sharing would help sales by allowing users to hear music and decide if they liked it before purchasing. However, the court found Napster guilty on all counts. Napster appealed to the Court of Appeals for the 9th Circuit but lost, though the appeals court recognized that Napster could be used for many purposes which did not constitute or facilitate copyright infringement. Napster was ordered to block access to infringing materials, but found this technologically and practically unfeasible; they shut down in July 2001 and eventually filed for bankruptcy. The service was restarted some time later under new ownership as Napster 2.0, a service offering legal copies of music files for sale, but it has never regained the popularity it had enjoyed as a free service.

Today, there are numerous services which offer legal copies of music. One popular example is the iTunes music store, which sells songs to be played on its popular iPod music players. Microsoft offers a similar service, as do many other companies. There are also still many copyright-infringing sites and services, both better and lesser known; some will be briefly discussed later in this entry. Lawsuits continue as each one is discovered by the music industry, and the music industry and other industries continue to lobby government for changes to legislation and harsher penalties for copyright infringement and theft of intellectual property. But it is difficult to keep up with the

sheer volume of such sites, and some are better than others at hiding their activities from unwanted eyes.

Currently, BitTorrent is one popular technology used for downloading files. There are near-innumerable sites which make use of BitTorrent technology, for legal purposes or otherwise. While some such sites (such as the now-defunct Oink) have been shut down, others proliferate. It is impossible, in any practical way, to keep up with the sheer volume of sites which offer material (both legal and in violation of copyright) for downloading. In BitTorrent sites, the site acts as an organizer and indexer, and does not provide files for downloading. Rather, BitTorrent sites offer metadata giving the location of files being offered for downloading, and checksums which can be used to verify the integrity of the file once a download is completed. Pirate Bay, one popular BitTorrent tracker (as systems offering BitTorrent technology, file metadata and locations, and checksums are called), offers indexes to sites where one can download music, movies, games, and software. Pirate Bay has been the subject of repeated legal actions, but the founders assert that they are not participating in copyright violation. Peter Sunde Kolmisoppi, speaking on behalf of Pirate Bay to *Wired* magazine, compared Pirate Bay to Google, saying “We’re just a general purpose search engine and torrent-tracking system. You can put whatever you want on the Pirate Bay. We don’t participate in how the people communicate with each other. We only participate in bringing the possibility to communicate and share files.”^[10] Lawyers for various plaintiffs disagree.

As well, some sites are located in other countries, and therefore not bound by U.S. law; many countries (notably Russia) refuse to recognize many international copyright agreements or restrictions. Other sites have relocated to, or are located in, countries where they feel they are less likely to be prosecuted for copyright infringement. Pirate Bay moved to a double-blind distributed server model; the founders provided servers to other people without telling them the content included Pirate Bay, and those people rented space for the material without telling the founders where the servers were.^[10]

Another way in which music files (and many other types of files) can be shared is through file-sharing services which allow users to post a file and notify a friend that the file is there for them to retrieve. These function in a manner somewhat analogous to a post office. One person uploads a file to the site, specifying a single person or a group of addressees to whom notification should be sent. One such service is known as YouSendIt. The recipient receives a notice via e-mail, much like the slip that the post office puts in your mailbox to tell you that a large parcel has been delivered to your local post office and is awaiting pickup. The addressee then clicks on the link in the e-mail or goes to the appropriate URL and enters specific information, and then retrieves the file. YouSendIt and similar services are popular as a means of avoiding the

file size restrictions on attachments which are common to many e-mail systems. This avoids any issue of posting a file to a server and making it widely available, and there is nothing illegal about offering services such as YouSendIt provides, but there are still no guarantees that the file being sent is legally obtained or copied or perhaps is open access.

A similar type of service allows you to upload a file to a server and leave it there, and then tell other people, by e-mail or by posting a notice on a blog or wiki, or in any number of other ways, to go to a certain link and download the file. Many music blogs provide links to uploaded files, and a wide array of search tools is available for use in locating such blogs. Finally, users can simply compress or zip files and send them directly to friends and colleagues as well. Such services are a highly convenient means of sharing information, and certainly not inherently illegal in any way; the question of illegality would arise only when considering the contents of a file attachment and whether permission to copy or share any materials for which such permission was even required had been granted.

One more way in which material is made widely available is through the creation and sale of pirated, illegal copies of CDs. This is an issue for software and for music alike, and for movies, there are pirated copies of videos, DVDs, or Blu-ray discs. This is an international concern, deeply disturbing to the associated industries—music companies, software producers, film companies, and others. In many countries, one can easily find the latest CDs from popular recording artists selling for a fraction of the price that would be charged in the United States, often before the official release dates. Pirated music or movies are not necessarily of the same quality as those that are legitimately produced: quality can vary widely, depending on a number of factors. Some copies are created from original tapes or files or other original materials that have been leaked to counterfeiters; some movies are copied simply by a person who sits through a viewing of a legitimate copy of a movie in a theater, with an illegal handheld video device, and then sells copies of the resulting movie. Similarly, copies of downloaded audio files may vary. RealAudio files purportedly were of poorer quality than purchased, legitimate CDs; however, with the advent of the MP3 standard, there have been considerable improvements in quality. Many people claim the quality of MP3 audio files remains inferior to legitimate CDs, but the popularity of downloading (whether legal or illegal) attests to the fact that many users consider it adequate. Pirated copies of music and movies are also not limited to foreign countries: one need only walk down the streets of New York (to use just one example) to find street vendors selling CDs and DVDs for far less than one would expect. Some may be legal, but police have frequently cracked down on pirated and counterfeit copies being sold.

Video: Movies, TV Shows, and More

Video sharing sites are among the most popular destinations on the Web. YouTube, Yahoo! Video, and many others offer users the opportunity to upload videos to their servers, and make them publicly available. Many people upload perfectly legal materials—home videos or other materials for which they own the copyright or for which they have obtained permission, or open access materials. Libraries have posted training and orientation videos, promotional videos, and much more on YouTube, sometimes as a way to avoid the bandwidth restrictions in place at their institutions, or simply as a way to ensure widespread distribution of their materials. One simple example of a YouTube video explaining how to use the library catalog of Brooklyn College is located at <http://www.youtube.com/watch?v=zLq1BzASsGU>; many libraries have posted extensive orientation and training videos. Companies post materials: to provide just one example, ARTStor, an art image database, has posted a video showing people how to register with and use their service at <http://www.youtube.com/watch?v=oAIQsiINlAA>. Political campaigns and political action groups post videos highlighting the achievements and purported virtues of some candidates, or pointing out the alleged deficiencies of others; the 2008 U.S. Presidential Election saw an explosion of material from individual voters and advocates, action groups, and even the campaigns of the candidates themselves; there were even “YouTube” debates, where during a number of the official debates, candidates took questions from voters who had posted their questions via their own YouTube videos. But there are also many instances of copyrighted materials being posted without permission having been obtained, in violation of the policies of the host site. These can be subject to takedown, but by the time the offending material is removed it may have been further copied or distributed.

YouTube has received a number of takedown notices under the DMCA. Several entertainment companies claimed that the site contained full-length versions or long clips from a number of popular TV programs, and that these had been posted by users who had not obtained permission from rights holders.^[11] YouTube was also sued by private individuals such as Robert Tur, who captured on tape the beating of trucker Reginald Denny during the 1992 riots in Los Angeles, and noted that this footage appeared on YouTube without his permission. Interestingly, “Tur did not claim that the site violated the DMCA. Instead, he invoked the 2005 Supreme Court decision in *MGM v. Grokster* and accused YouTube of building a network through the promotion of copyright infringement—i.e., piracy.”^[11]

However, YouTube had one advantage which had previously been unavailable to Napster. Congress has since added a provision to the DMCA, known as the Online Service Provider Safe Harbors provision (Section 512(c)).

Under this provision, YouTube is not liable for the actions of its users if it has posted a clear notice and takedown provision, which indicates that if copyright-infringing material is found and YouTube is notified that material on its site infringes copyright, it will remove the material. YouTube has such a posting, and removes infringing material when it is notified. This has not entirely stopped lawsuits: in July 2008, a lawsuit in the amount of \$779 million (USD) was filed against YouTube (owned by Google since 2006) by the Italian broadcaster Mediaset.^[12] In 2007, a \$1 billion copyright infringement lawsuit was filed against Google itself; the plaintiff was Viacom, which owns MTV networks and Paramount Pictures.^[12]

There are also a number of smaller sites that offer content which potentially infringes on copyright (presuming permission to post/distribute has not been sought). In 2007, Michael Arrington, coeditor of the popular Techcrunch weblog, wrote that:

Full length copies of well known TV shows and/or movies are readily available on a number of YouTube competitors. Watch, for example, *The Office* on DailyMotion, *Scrubs* on GoFish, or *South Park* on Veoh (update: GoFish and Veoh have apparently removed the shows ...). And if searching for the shows on these sites is just too much work, there are other sites that aggregate and organize this content, and embed it on their own sites. Watch any episode from any of the 11 seasons of *South Park* on Allsp.com. And new site VideoHybrid is in a class of its own, with dozens of full length movies and virtually every popular TV show. VideoHybrid even gives statistics showing exactly how many times copyrights have been violated.^[13]

The MPAA and various entertainment companies and television producers have been watching YouTube, Yahoo! Video, and many other sites, but not all well-known sites have yet been targeted. “It’s not clear if the MPAA and networks just aren’t focusing on these smaller video sharing sites yet,” Arrington also states, “or if DMCA notices are simply being ignored. These sites aren’t hiding out and trying to evade the law—they’re funded by well known venture capitalists and, in Veoh’s case, copyright holders. And GoFish is actually a public company.”^[13]

As noted, the sale of pirated counterfeit DVDs and Blu-ray discs of movies, whether internationally or locally, is of great concern to the motion picture industry. Companies get no revenue from pirated movies, and many claim that the sometimes poor quality of the counterfeit materials could damage the movie producers’ reputations and standards. But again, it appears to be nearly impossible to determine or even estimate with any degree of certitude how much piracy is taking place. The entertainment industry claims that “piracy costs the United States between \$200 and \$250 billion annually in lost sales, and 750,000 jobs.”^[14] However, there does not appear to be independent verification of these figures.

Published Works

Creators and distributors of other published works, such as book publishers and authors, are also concerned about issues of piracy. If the published works are normally in electronic form, the potential piracy issues and opportunities are similar to those for other digital materials. If the published works are in print, digitized copies of the original print works are at issue. (Of course, book “piracy” can also be accomplished by making additional print copies of print volumes, via such means as obtaining books and creating copies or additional print runs for sale. However, since this entry focuses on piracy in digital media, this will be excluded from discussion.)

One example of controversy surrounding digitized copies of print works is the Google Print Library Project. When Google announced in late 2004 that it would be working with the University of Michigan, Harvard University, Stanford University, the New York Public Library, and Oxford University to scan all of or portions of their collections (Harvard, for example, provided only a portion of their vast collections, and included no books which were in copyright), the reaction was swift. The Authors Guild, which is the largest society of published writers in the United States, termed this project a “brazen violation of copyright law”^[15] and promptly sued Google. The Association of American Publishers (AAP) and their president, former Democratic congresswoman Patricia Schroeder, agreed, arguing that Google’s business model for this project was to “take everything you create, for free, and sell advertising around it.”^[16] Five major publishers (McGraw-Hill Cos., Pearson Education Inc., Penguin Group (United States) Inc., Simon & Shuster Inc., and John Wiley & Sons Inc.) filed suit as well, and the French Publishers Association (representing over 400 French publishers) and La Martiniere Group also filed suit. Google argues that only material which is out of copyright will be freely available to all users; that books which are indexed in this project and which are still under copyright will be held to a limited display of “snippets” of text; and that creation of an index such as they avow the Google Print Library Project to be constitutes fair use under copyright law. As well, they state that any publishers who do not wish their books included can request removal of individual titles by contacting Google. Some authors support the lawsuits, but others have opposed it, arguing that it can only help them if potential readers find it easier to discover their books, even in “snippet” form. Several additional university libraries later joined the Google Print Library Project. The entire project, including other stakeholders in addition to libraries, became known as the Google Book Search project.

On October 28, 2008, Google announced that it had reached a settlement with U.S. publishers and authors, for \$125 million.^[17] The settlement agreement runs to approximately 300 pages, not all questions have been

resolved, and reactions have been decidedly mixed. Harvard University Librarian Robert Darnton asserted that potential limitations on access to and use of materials could make it impossible for Harvard to continue to participate; Paul Courant of the University of Michigan wrote that the agreement changed Google from a “universal digital library” to a “universal digital bookstore” because of fees which would be charged to access more than small portions of books in copyright.^[18] Other reactions, positive and negative abound. A discussion of the settlement could be fodder for an entire book in itself, and is beyond the scope of this entry, but it is worth noting that issues of fair use were not resolved for one and all. Writing a legal analysis for the Electronic Frontier Foundation (EFF), Fred von Lohmann asserts that

... this outcome is plainly second-best from the point of view of those who believe that Google would have won the fair use question at the heart of the case. A legal ruling that scanning books to provide indexing and search is a fair use would have benefited the public by setting a precedent on which everyone could rely, thus limiting publishers’ control over the activities of future book scanners. Instead, only Google gets to rely on this settlement, and the agreement that makes many concessions that a fair user shouldn’t have to make.^[19]

By contrast, the Open Content Alliance, a book scanning project sponsored by Microsoft and Yahoo and working with a number of other academic libraries, including libraries from Columbia University and the University of Toronto among others, deals only with books currently in the public domain. Google News Search was also entangled in a lawsuit in Belgium, where Copiepresse, an organization managing a number of Belgian newspapers, was objecting to its use of content, including headlines, in Google News Belgium. The decision in that case went against Google, and Google was ordered to remove Copiepresse articles. Other legal action is still pending.

Another example of a controversy surrounding books and journals is the lawsuit against Georgia State University (GSU), launched in 2008 by the American Association of University Publishers (AAUP). GSU made available, through electronic reserves and its password-protected course management system, digital copies of articles in journals to which they subscribed. The AAUP claims as well that professors linked directly to some of the resources through open Web pages; however, at the time of this writing, it is unclear whether or not specific examples of this latter practice were available. The lawsuit alleges widespread copyright infringement; GSU counters that these practices are permissible under fair use. The case remains before the courts. Many universities and colleges have made deals with publishers to permit e-reserves, either in response to threatened lawsuits or in efforts to avoid them;

Cornell University, in particular, was an early player, and developed a set of comprehensive electronic course content guidelines, available online at http://www.copyright.cornell.edu/policy/Copyright_Guidelines.pdf.^[20]

LEGISLATIVE FRAMEWORK

Before 1964, laws relating to piracy of intellectual property covered only printed works; in 1964, the U.S. Copyright Office began including software for registration. In 1974, the National Commission on New Technological Uses (CONTU) began to try to determine whether new technology growth was out-pacing existing copyright law, and what protection should be extended; in 1980, the Copyright Act was amended to explicitly include computer programs. In 1990, Congress approved the Software Rental Amendments Act, which “prohibits the commercial rental, leasing or lending of software without the express written permission of the copyright holder. An amendment to Title 18, of the United States Code, was passed by congress in 1992. This amendment, known as Public Law 102-561, made software piracy a federal offence and instituted criminal penalties for copyright infringement of software.”^[21]

In 1998, the DMCA became law. The reasoning behind this law was that copyright holders needed better laws to protect their rights and combat piracy.

DMCA provided those tools – and also created a whole new class of crime that causes unfortunate side effects. The Electronic Frontier Foundation (<http://www.eff.org>) posted *Unintended Consequences: Three Years Under the DMCA* in May. The executive summary argues that DMCA’s anti-circumvention provisions (Section 1201) have not been used as Congress envisioned. Congress was after pirates and wanted to ban black boxes, but the provision has been used to stifle legitimate activities. According to EFF’s report, Section 1201 chills free expression and scientific research, jeopardizes fair use, and impedes competition and innovation. The summary provides examples of otherwise-legitimate activities made impossible by Section 1201 (e.g. fast-forwarding through commercials before a DVD movie), real-world examples of the harm done by DMCA, including self-censorship for fear of violating the act, scientists unwilling to come to the U.S., the assault on fair use represented by copy-protected pseudo-CDs, and more.^[22]

As one media education professor complains, “The DMCA trades the broad fair use doctrine for a series of narrowly defined exemptions”^[23] and there is no exemption for media education; theoretically, for every usage of media work for educational purposes, a media education professor would need to research the rights holders and obtain written, explicit permission—a tiresome and lengthy process. Also in 1998, shortly after the passage of

the DMCA, the *Sonny Bono Copyright Term Extension Act* was passed into law. This law extended copyright terms by 20 years, causing many materials to take much longer to become available in the public domain.

In May, 2008, the U.S. District Court in Seattle ruled in favor of a man named Timothy S. Vernor who had posted a copy of Autodesk software on the Internet auction site eBay for resale. Autodesk had requested summary judgment against Vernor for contributory copyright infringement, but the Court ruled in his favor, and stated that the first sale doctrine of copyright law applied. The Court found that first sale applied.^[24] This is the same principle as that by which used book stores operate: the publisher of a book gets nothing when a reader resells his copy of a novel to a used book store, as the publisher has already benefited from revenues received from the first sale. The case may be appealed, though, and there is much remaining confusion as to what constitutes legal or illegal practice regarding resale of technology. It is confusing, because contributory copyright infringement is essentially that with which Pirate Bay was charged. Pirate Bay charges nothing (and various materials loaded on its servers may not be under copyright, or may be open access), and Mr. Vernor was reselling a piece of software. Yet each was charged similarly, in very different environments. The legislative framework for copyrighted, non-open access software is often still unclear—as is indeed the case for other copyrighted materials. Additionally, the legislative structure in which intellectual property exists and operates varies widely depending on the country in which the property is created or utilized. Laws can be quite different from one country to the next, and international law is not accepted everywhere.

Pirate Bay is currently facing charges that it is “promoting other people’s infringement of copyright laws”^[10] and there is a movement by Swedish Culture & Justice ministers to give Swedish courts the power to force ISPs to reveal the Internet Providers (IPs) of their subscribers, in order to charge the subscribers themselves for copyright infringement.^[25] Pirate Bay continues to face charges in Swedish courts, and people and organizations continue to appeal to the Swedish government to address the issues raised by Pirate Bay, even though they have ostensibly moved all of their servers out of Sweden.

According to some reports, in China, “bootleggers selling 75 cent DVDs dominate 95 per cent of the market”^[26] and in an effort to combat this trend (which the studios claim cost them up to \$3.8 billion a year), some companies have begun slashing the prices of legitimate DVDs. For example, “Time Warner is reducing the price further, to \$1.50 or less, and releasing movies in as little as 15 days after theater runs.”^[26]

The Software Industry Association of America (SIAA) monitors auction sites, and insists that pirated materials be removed, “either the DMCA’s notice-and-takedown process or eBay’s VeRO (Verified Rights Owner) program.”^[27] Microsoft has launched several lawsuits against vendors

using auctions sites to sell pirated software; “suits were brought in the U.S., Germany, the Netherlands, France, and Britain, as well as Argentina, Australia, Belgium, Korea, Mexico, and Poland.”^[28] FileMaker, Symantec, and other companies have also launched similar suits.

In the European Union (EU), however, the top court (the European Court of Justice) recently ruled, in a dispute between the Spanish music rights holders association Promuscaé and Spain’s top telecom operator Telefonica, that EU countries were permitted to refuse to disclose names of file sharers on the Internet in civil cases. Telefonica argued that it was only required to disclose subscriber information in criminal cases, and the court said that “Community law does not require the member states, in order to ensure the effective protection of copyright, to lay down an obligation to disclose personal data in the context of civil proceedings.”^[29] In Belgium, Copiepresse won its lawsuit against Google news; in Italy, the lawsuit against YouTube proceeds. Requirements of service providers to reveal information about customers vary widely, and legal decisions regarding fair use and copyright continue to vary as well from country to country.

In the United States, various commercial ISPs have been accused of BitTorrent throttling—refusing to allow access to known BitTorrent sites, regardless of whether material being accessed is legal or copyright-free, or of choking access to such an extent as to reduce download speed to a crawl, in hopes of limiting or discouraging user access. ISPs generally deny this practice is occurring, but some are currently under investigation for the practice. Notably, Comcast has been cited for BitTorrent throttling, and the Federal Communications Commission (FCC) asserts that this practice violates Net Neutrality rules. However, it is unclear whether the FCC has authority to actually do anything about BitTorrent throttling, or take any action against Comcast.^[30] ISPs have also sometimes been asked to turn over subscriber information, especially when there are allegations of piracy or other illegal practices, and some have complied, while others have refused and taken the issue to court, with varying results. In some countries, notably China, the Internet is filtered, and many sites cannot be accessed; Pirate Bay is apparently among those blocked by the Chinese government.

Universities and colleges have in many cases become perplexed not just about what they can legally provide in terms of electronic course reserves, but also about what professors may do in terms of excerpting materials for their classes. How large a clip from a film can they show to their class, for example, without having to obtain public performance rights? Will they risk being accused of piracy, or potentially charged, if the clip is too large? With so much still before the courts and the government, and many laws and regulations still unclear, many potential users of materials are afraid of risking a lawsuit, and claims of a “chilling effect” are common. In an attempt to alleviate this, the Center for Social Media of the School of Communication

of American University has created a set of guidelines for copyright and fair use in documentary film, available online at http://www.centerforsocialmedia.org/resources/fair_use.^[31] However, especially in the digital world, the exact parameters of fair use remain difficult to ascertain. A number of organizations which dispute the strong actions of many copyright holders or organizations representing copyright holders claim that not only does strict enforcement infringe upon fair use and cause a chilling effect, it also infringes upon free speech, as writers and artists and filmmakers may be unwilling to risk being sued.^[32]

The legislative structure in which music, TV, and motion picture companies attempt to protect their material from unauthorized distribution or piracy is also somewhat unclear. The DMCA seems to lean heavily toward support for rights holders (some claim to the detriment of other stakeholders) but the Online Provider Safe Harbor clause does protect sites and their owners from unauthorized behavior by their users, if they have a clear “notice and takedown” policy. And yet, video and music sharing sites proliferate, and many offer free and easy access to copyrighted material. Is the MPAA not focusing on smaller sites? Or are the sites getting takedown notices, and ignoring them? Why, as aforementioned, are some of the sites public companies, or “funded by well known venture capitalists and, in Veoh’s case, copyright holders”^[13] if there is fear of legal reprisals? As well, the RIAA in particular has focused strong efforts on targeting universities and colleges, asserting that students are heavy users of pirated music. On May 3, *Wired* magazine noted “universities in the US are experiencing a ‘20-fold increase’ in the number of takedown notices from the RIAA in the last ten days. Indiana University reports 80 notices a day, but they say their traffic hasn’t increased significantly over the same time period.”^[32] There have been mixed responses from the universities and colleges that have been thus targeted; various responses and recent changes to RIAA actions will be discussed in the next section.

Finally, there is also a lack of clarity surrounding access to and distribution of electronic copies of journals, journal articles, and books. Back in the days when all books and journals were published in print form, libraries had long-established and clear policies and procedures. They might vary from library to library—but you knew what to do, whether you were a publisher, a librarian, or a researcher. Books and journals were published and sold in print form. Libraries purchased the materials (whether outright or via a standing order or subscription), and processed them according to whatever procedures they had established. Materials were made accessible to library patrons—again, according to whatever policies the library had established. Some institutions had “open stacks” and patrons could browse; others had closed stacks and library staff would retrieve requested materials. When photocopyers came into existence and became commonly used in libraries, researchers might copy articles or chapters

they needed. Hopefully they would follow fair use principles as to the amount of material that could be copied, but whether they did or not, the principles and legal issues were generally fairly clear, and libraries frequently posted signs informing patrons of any restrictions. Interlibrary loan departments receiving article requests knew how much they could copy and send.

In a digital world, the legislative issues are again somewhat murky, and many questions have arisen. Articles in electronic form are much more easily transferred, copied, and shared. This is perfectly legal in many circumstances, but often there are disputes. For example, some licenses for electronic journals and databases refuse to permit libraries to use articles within these databases for interlibrary loan purposes, or they may place a variety of restrictions on the usage of the articles. Some will permit a library to print a copy of an article from an e-journal and use the printed copy to fill the request, but will not permit an electronic copy to be e-mailed. There are many possible permutations of restrictions that can be imposed. Some publishers wish to restrict access to their e-journals and databases by imposing such restrictions as limiting access to a single terminal or a set number of terminals within a library; some publishers refuse to permit remote access. As well, some publishers require institutions, including libraries, to sign agreements which require them to keep the terms of particular licenses confidential—so theoretically, you cannot even compare the deal your library has signed with that signed by another library.

As for e-books, procedures and restrictions vary by publisher here as well. Many publishers place restrictions on how much of a book can be saved, downloaded, and/or printed by a particular user or from a particular computer IP address. Some put restrictions on the number of simultaneous users for each item. Some object to e-books being used by entire classes unless multiple copies or user licenses are purchased. Some attempt to restrict access to e-books or e-journals in course management systems or online course systems such as Blackboard.

Again, one need only look to the aforementioned lawsuit against GSU for one example of a dispute between publishers and an academic institution as to how electronic materials may be used for online courses; many institutions (such as Cornell University and its libraries, for example) have worked out detailed agreements. Publishers are concerned about potential lost sales if their product is copied or shared—and this is much easier to accomplish when the material in question is in electronic format.

The recent settlement in the Google Book Search seems to impose a number of restrictions on access to and usage of works in their database, and reactions have been mixed. Many people have praised the increased overall access to digital copies of books. However, in an editorial

written for the online *Library Journal*, Editor in Chief Francine Fialkoff criticizes restrictions that will affect libraries and their patrons:

One public access terminal per public library building. Institutional database subscriptions for academic and public libraries that secure once freely available material in a contractual lockbox, which librarians already know too well from costly e-journal and e-reference database deals. No remote access for public libraries without approval from the publisher/author Book Rights Registry, set up to administer the program. And no copying or pasting from that institutional database, though you can print pages for a fee. Of course, you can always purchase the book, too.

Those are just a few of the choice tidbits from the 200-page settlement in the Association of American Publishers (AAP) and Authors Guild three-year-old suit against Google, drawn from Jonathan Band's "Guide for the Perplexed: Libraries and the Google Library Project Settlement."^[33]

Fialkoff emphasizes that the settlement document does include provisions and specifications that outline what libraries are and are not permitted to do, and that in many instances, access to materials should become more widespread. However, she continues by stating that

ultimately, it is the restrictions that scream out at us from the miasma of details. Even the libraries that were initial partners (or those that become partners) in the Google scan plan don't fare well. They get a single digital copy of each book from their collection—mind you, they've paid for these books already—and can print a replacement copy only if a new copy isn't available at a "fair price." They can allow faculty and students to "read, print, download, or otherwise use five pages of any book in its LDC" (library digital copy set) for books "not commercially available," but they can't use the LDC for interlibrary loan or e-reserves. There are all kinds of potentially costly, nightmarish administrative minutiae, including a security plan and annual audits of usage and security.^[33]

Intellectual property and the rights of creators, publishers, vendors, and users are all tied in closely with issues of piracy and other (sometimes arguably) unauthorized or illegal access to and usage of digital materials of all types.

A related controversy is the issue of whether research which is accomplished and published partially or wholly with the assistance of public funding, such as grants, should be free of charge, either immediately or after a period of time. One interesting, and ongoing, case in point is the controversy surrounding the National Institutes of Health (NIH) Public Access Policy. In December 2007, the United States Congress and President George W. Bush authorized the NIH to require that any articles which were a result of research that had received public funding (such as an NIH grant, for example) be deposited, after a period

of one year, in the PubMed Central archive. Articles need not be deposited immediately; a lag period of one year from time of publication was granted. This allowed publishers of the scientific journals which had accepted and printed the articles to continue to have sales of their journals, but researchers who were willing to wait a year would ultimately be able to obtain free access to the specific articles containing research results which had been supported by public funding. The American Association of Publishers fiercely opposed the NIH Public Access Policy. Subsequently, on September 9, 2009, Representative John Conyers (then Chairman of the House Judiciary Committee) introduced a bill (H.R. 6845, the Fair Copyright in Research Works Act) “designed to strike down the NIH Public Access Policy and prevent other federal agencies from implementing similar policies. According to the text of the bill, ‘No Federal agency may, in connection with a funding agreement, impose or cause the imposition of any term or condition that requires the transfer or license to or for a Federal agency of any right provided under’ copyright law.”^[34] Of course, if the Public Access Policy is struck down, then articles resulting from publicly funded research would be treated as any other articles, and “piracy” of such materials (or any other unauthorized action) would be subject to the same laws and penalties.

In December 2007, the Prioritizing Resources and Organization for Intellectual Property Act (variously shortened and referred to as PROIPA or PRO IP Act or PRO-IP Act) was introduced. In May 2008, it passed the House Judiciary Committee; this is the first step, though, and if the bill fails to pass both the House and the Senate before the end of the year, it would need to be brought forward anew in 2009. The bill is cosponsored by many legislators, including the Chair of the House Judiciary Committee, Representative John Conyers, Jr. and the Chair of the Subcommittee on Courts, the Internet, and Intellectual Property, Representative Howard Berman. Some of the provisions of PROIPA include massive reforms to copyright and patent enforcement. Statutory damages would be raised, and there would be a lower threshold for prison terms for copyright offenses.

In its initial form, the bill included a controversial rule which allowed litigants to stop treating compilations of copyrighted works as a single work. Thus, a music label could seek many times the normal statutory damages if they sued someone for copyright violation involving copying an album: every song would be treated separately. Similarly, for magazines or newspapers, every article would be treated separately. This rule, Section 104, was removed by Representative Berman before the bill went to the full Committee, after hearings during which proponents of the section argued that allowing works to be treated as compilations devalued individual articles or songs or other portions of a compilation. Opponents of the provision argued that statutory provisions for damages

were already high, and that there was no proof any rights holder had ever been injured by insufficient compensation due to the existence of the compilations rule. Accordingly, the provision was removed.^[35] The bill also provides for the establishment of an Intellectual Property Enforcement Division in the U.S. Justice Department.

Issues of copyright, intellectual property, piracy, and related issues (such as the issue of whether open access to publicly funded research shall be mandated or optional) continue to be issues of hot debate and ongoing interest to a wide variety of stakeholders.

RESPONSES

Library associations, intellectual property scholars, technology associations, and many others are unified in opposition to the PROIPA legislation and to various provisions of the DMCA. The Library Copyright Alliance, the Computer & Communications Industry Association, and the EFF, among others, have all written to Congress to express this opposition and dispute various claims made (such as claims about how widespread piracy is, and how great its costs are). In an essay on the difficulties created by raising the bar on getting permissions for usages that were clearly previously considered fair use, Peter Decherney argues that “If you are a documentary filmmaker, insurance companies and distributors have raised the permission bar to an impossibly high level. Documentary filmmakers are frequently expected to clear every use of copyrighted and trademarked material even when those uses are plainly allowed by the law.”^[23] He also goes on to describe the difficulties now inherent when professors wish to show clips of movies for classes; in many cases, they risk being in violation of copyright, though usage of portions of work for nonprofit, educational purposes had generally been considered to fall within the range of fair use in predigital times. As previously mentioned, GSU is battling the AAUP, which claims that copyright was infringed by the way in which GSU made electronic course reserve materials available.

Some ISPs are also unhappy—and not just those who have been accused of BitTorrent throttling. In the United States, to date, ISPs have generally not been held responsible when copyrighted materials are illegally made available via their servers. They must comply with takedown notices, but are not held responsible for the behavior of their users in posting the infringing materials in the first place. But this is not the case everywhere. In February 2008, *Business Week* reported that proposed legislation in Britain could turn ISPs into a different kind of ISP—Internet Service Policemen. ISPs would be held responsible for the behavior of their customers, ISPs who failed to halt illegal downloads would be sanctioned, and ISPs could be compelled to turn over information about customers who

infringed intellectual property rights.^[36] These proposals are still in their early stages. However,

the tough ISP stance has already set off alarms. Industry analysts and legal experts warn the proposals could hurt legitimate downloading of Internet content and saddle ISPs already suffering from thinning margins with much higher costs. Equally important, the proposal raises privacy and free-speech issues. Under long-standing common carrier principles, communication companies aren't legally responsible for the content of the traffic they carry over their wires and wavelengths even if it's a conversation between robbers planning a crime or somebody downloading child porn. Britain's ISP plan could upend this bedrock principle by turning carriers into cops.^[36]

At present, it is not technologically possible to distinguish between legal and illegal content being carried across the ISPs; imposing such restrictions could lead to extensive content monitoring by ISPs, jeopardizing user privacy. And even if the content of every file was monitored, who is to say that a user transmitting a file containing a research article, a scanned chapter of a book, a song, a video, or any other digital material, has not obtained permission to do so?

Universities and colleges are themselves ISPs, to their large communities of faculty, staff, and students. The RIAA has targeted postsecondary educational institutions, claiming that music piracy is rampant among students. Tactics espoused by the RIAA have included sending letters to university administrators demanding that the university reveal the identities of students using computers with various IP addresses; demanding that universities filter their Internet access to exclude peer-to-peer sites; and sending notices to universities asking them to pass along to individual students prelitigation letters demanding that they pay up to \$3000 or face prosecution in court. Since February 2007, the RIAA "has provided some 4,000 such letters to more than 150 colleges and universities. The letters offer the students what they call bargain settlements if they act fast, by punching in a credit card number at <http://www.p2plawsuits.com>."^[32] The RIAA is also "backing legislation in states such as Illinois and Tennessee that would require schools that get a certain number of notices to begin installing deep packet monitoring equipment on their internet and intranets."^[32] As well, the RIAA had hired a company called MediaSentry to gather information about students and other potential music copyright infringers. MediaSentry would "troll the Internet in search of people who upload large amounts of music. The information that MediaSentry collected became an integral part of the RIAA's aggressive litigation strategy."^[37]

However, MediaSentry was the cause of considerable controversy, including allegations by lawyers acting (for students and for some academic institutions opposing the RIAA in court) of invasion of privacy. In a report in the *Wall Street Journal*, Ray Beckerman, a lawyer who

"maintains the Recording Industry vs. the People blog and who has represented more than a dozen clients fighting the RIAA"^[37] was quoted as citing "MediaSentry's practice of looking for available songs in people's file-sharing folders, downloading them, and using those downloads in court as evidence of copyright violations. He says MediaSentry couldn't prove defendants had shared their files with anyone other than MediaSentry investigators."^[37] Other tactics MediaSentry allegedly employed included "scan[ning] for anyone downloading files through LimeWire and Ares."^[38] In 2008, the RIAA ended its agreement with MediaSentry, without disclosing its reasons, switching instead to Danish firm DtecNet Software ApS. Officially, the RIAA stood by the methods MediaSentry used, "citing University of Washington research released last year that concluded the company's methodology incorporates 'best practices.'"^[37]

Responses (to RIAA actions) from colleges and universities have varied widely. In some cases, the university in question has simply immediately turned over all student information. Of course, this is easier if the student is always using the same computer, i.e., in a dorm room. Even in these cases, though, if there are two students sharing a dorm room, the RIAA has been known to sue both students, though only one may be guilty of infringement. This was the case when, in 2004, the RIAA sued two students attending Portland State University. The University responded to the subpoena from the RIAA by providing personal identifying information about two roommates. It could not determine which student was using the computer in the room, so it provided information on both students. One student, Delaney Conway, was not the person using the computer at all, yet the record company lawyers insisted that she pay \$4500. She refused, and determined to fight the case. The case against Ms. Conway was finally dropped, and her roommate paid a settlement fee. Other universities have refused to provide any identifying information, citing either student privacy issues or, in some cases, the impossibility of telling which student was using which computer. The latter is particularly difficult to determine when the computers are public, or available to many people, as is the case in a computer lab or library.

Some universities have fought back on behalf of their own students, or, in one case, on behalf of non-students accused of piracy. The University of Maine's Cumberland Legal Aid Clinic has fought back against the RIAA on behalf of its students. In Oregon, the University of Oregon, with support from the State Attorney General, filed a motion to quash the RIAA's subpoena demanding student identities, explaining that

it is impossible to identify the alleged infringers from the information the RIAA has presented: 'Five of the seventeen John Does accessed the content in question from double occupancy dorm rooms at the University. With

regard to these Does, the University is able to identify only the room where the content was accessed and whether or not the computer used was a Macintosh or a PC . . . The University cannot determine whether the content in question was accessed by one occupant as opposed to another, or whether it was accessed instead by a visitor.'

The AG's motion further argues that "Plaintiffs' subpoena is unduly burdensome and overbroad. It seeks information that the University does not readily possess."^[39] The University of San Francisco School of Law has taken action against the RIAA even further, and attorneys-in-training from its Intellectual Property Law Clinic, under the supervision of law professors, are helping clients outside of their own community, pro bono. "They reached out 3000 miles to get involved in *Elektra v. Torres* and *Maverick v. Chowdhury*, two cases going on in Brooklyn, NY, against non-college defendants."^[40] Some additional complications include the fact that the Family Education Rights Protection Act (FERPA) makes it illegal to reveal most private information about students; that IP addresses of individual computers may be dynamically allocated, rather than static, and thus it can be impossible to identify with any certainty who used what computer at what time, and for what purpose; and that IP addresses can be falsified by clever people wishing to hide their identities and actions.

Results to such cases have been mixed. In some cases, various privacy arguments have not held; in others, judges have strenuously objected to some RIAA tactics and actions, even to the extent where some judges have threatened to fine RIAA lawyers. There have been allegations in court that MediaSentry violated privacy and engaged in unlicensed data mining to gather information about defendants or those suspected of engaging in illegal downloading. A defendant named Tanya Anderson filed an amended complaint against the RIAA, seeking to stop them from "continuing to engage in criminal investigation of private American citizens."^[41] Again, this case is ongoing; it had begun as a the countersuit to the lawsuit where "RIAA lawyers tried to grill a 10-year-old girl, only later to drop their case for lack of evidence and have the mother sue them for malicious prosecution."^[41] In a case involving four Boston University students, the EFF filed a brief in support of the students, who were represented by other lawyers. In that case, the *Boston Globe* reported on April 4, 2008 that

US District Judge Nancy Gertner ruled this week that the university cannot turn over the names of students to several major record companies that sued for the information until she can do a more in-depth review. The ruling, for the moment, quashes the companies' efforts to hold the students liable for copyright infringement, which could have resulted in thousands of dollars in fines. Lawyers who supported the students said the decision would make

it harder for record companies to win some 20,000 similar cases they have brought nationwide.^[38]

Judge Gertner's ruling forbade Boston University from "turning over names until it shows her its Internet service agreement with students so that she can review what privacy protections, if any, it affords."^[38] One recent development in the RIAA strategies is especially interesting. In December 2008, the RIAA decided to cease filing lawsuits against individuals engaging in downloading, though it plans to continue with cases currently filed; instead, it will continue its discussions with ISPs to attempt to reach agreements on file monitoring.

FUTURE DIRECTIONS AND CONCLUSIONS

Illegal downloading of music, software, visual images, videos, films, electronic books, electronic journal articles, or any digital material is theft. But what constitutes "illegal" downloading? This is, in many instances, unclear. "Fair use" has long been part of copyright law, and some allegations of piracy are met with a defense that the copying or usage or sharing falls within fair use. What, in a digital environment, constitutes fair use? There are many complications to various cases, and many debates about the appropriateness of various responses and actions. Arguments have become quite heated on all sides, in the courts and in the popular press. There are many details to be worked out by the courts, and it is likely that these battles will continue for some time.

Many technological solutions have been attempted, including copy protection added to DVDs and CDs; thus far, all solutions seem to have been vulnerable to hacking, and none appears to have succeeded. It may indeed be illegal to circumvent such protective technology; that does not mean it is not possible, and once a means to circumvent the protection is devised, one can be fairly well assured that it will be posted all over the Internet within hours.

Solutions have been proposed that would see ISPs held legally responsible for the content of what is posted on their services; arguments made against this include considerations such as privacy rights or freedom of speech. There have been suggestions that persons caught illegally downloading music or films should lose access to their Internet service; some schools have instituted such policies, and there are proposals being floated to have commercial ISPs follow suit. Alternatively, there have been proposals to have ISPs levy monthly fees on broadband customers and turn these fees over to the RIAA, the MPAA, the SIIA, the BSA, and/or other groups. Fees have been proposed on blank media, such as recordable CDs, as well. In some cases, reducing the prices of software, music, and movies is being attempted; the success of this strategy has not been fully documented to date. The only

certainty appears to be that digital piracy (and even the definition of what constitutes digital piracy) will remain a controversial subject for many years to come.

Plagiarism of Print and Electronic Resources

Zorana Ercegovac

InfoEN Associates, Los Angeles, California, U.S.A.

Abstract

This entry discusses plagiarism of printed and electronic resources, explores definitions of plagiarism, and provides a literature review. The entry then discusses the following issues: how prevalent plagiarism is, faculty's attitudes toward plagiarism in general, cyber-plagiarism in particular, predictors that correlate with plagiarism, and how to cope with plagiarism. The entry offers suggestions for future research on the topic of plagiarism.

INTRODUCTION

This entry concerns itself with plagiarism of printed and electronic media. It starts off by reviewing literature on definitions of plagiarism, and answering questions as to how prevalent plagiarism is, faculty's attitudes toward academic dishonesty in general, and plagiarism in particular. Predictors that associate with acts of plagiarism are discussed under the headings of social factors and individual differences. To answer the question, what is done to cope with increase of plagiarism incidents, this author summarizes theories of ethical reasoning as well as various approaches, such as instructional techniques and software detection programs. The entry concludes with an agenda to be considered for future research.

DEFINITIONS OF PLAGIARISM

Merriam-Webster's Collegiate Dictionary^[1] defines plagiarism as the act of stealing and passing off (other creators' ideas as expressed in words, pictures, music) as one's own; use (another's production) without crediting the source; to commit literary theft: present as new and original an idea or product derived from an existing source. The *Oxford English Dictionary*^[2] defines plagiarism as the "wrongful appropriation or purloining, and publication as one's own, of the ideas, or the expression of the ideas (literary, artistic, musical, mechanical, etc.)." The OED cites numerous sources that mention plagiarism in different historical contexts starting with a citation from 1621.

Many articles that write about the concept of plagiarism also talk about related, but very distinct topics such as fabrication, academic integrity in the context of ethics and moral development; vocabulary also pertains to fair use, copyright and intellectual property, various cheating behaviors, and honor code violations by different user populations in different countries. While the acts of stealing, corruption, lying, piracy, and forgery are normally

punished by law, stealing intellectual or artistic content (e.g., textual, musical, visual, software code) from another person and passing them off as one's own, sometimes remains undetected and unpunished. Dames in his 2007 article "Understanding plagiarism and how it differs from copyright infringement," states that "plagiarism allegations can be much more damaging [than copyright infringement that can result in financial damages or even jail] to a person's professional reputation than allegations of copyright infringement" (p. 26)^[3].

Numerous other writers have attempted to define the concept of plagiarism. In an excellent bibliography on plagiarism that reviews nearly 700 books and scholarly articles written in English between 1900 and 1995, Anderson discusses different definitions in the historical, cultural, and disciplinary contexts.^[4] The annotated bibliography is organized chronologically, following an extensive Introductory section, and discussed under four sections: 1) trends in definition; 2) follow the money; 3) detection, proof, and punishment; and 4) protecting one's property.

Angélil-Carter, in her work *Stolen Language? Plagiarism in Writing* (2000), discusses the historical development of the notion of plagiarism, along with copyright.^[5] From the British perspective, she tries to convey that plagiarism is an elusive concept and has been treated differently in different contexts. As Angélil-Carter writes in her Introduction, she wanted to "understand plagiarism differently," and to communicate that understanding to teachers and writers of academic discourse (p. 3).

Two college English professors, Rebecca Moore Howard and Margaret Price also address the concept of plagiarism from multiple perspectives. Howard discusses plagiarism from the perspectives of authorship, pedagogy, and scholarship; in closing, she proposes policy on plagiarism, as well as advice for students and teachers.^[6] Howard characterizes plagiarism as "patchwriting" if students are "copying from a source text and then deleting some words, altering grammatical structures, or plugging in one synonym for another." (p. xvii)^[7]. Price considers

plagiarism in a given time, academic community, workplace, defined in a specific discipline, rather than as an absolute concept across different cultures and communities.^[8]

Not All plagiarism Is Perceived Equally

Burke distinguishes among the four forms of cheating: *Cheating*, according to Burke, is “intentionally using or attempting to use unauthorized materials, information, or study aids in any academic exercise.” *Fabrication*, Burke writes, is “intentional and unauthorized falsification or invention of any information or citation in an academic exercise.” *Facilitating academic dishonesty* is defined as “intentionally or knowingly helping or attempting to help another to commit an act of academic dishonesty,” and *plagiarism* is defined as “intentionally or knowingly representing the word of another as one’s own in any academic exercise.”^[9]

The Council of Writing Program Administrators, CWSA, thinks of plagiarism as a deliberate use of “someone else’s language, ideas, or other original (not common-knowledge) material without acknowledging its source.” This definition is extended to printed and digital materials, manuscripts, and other works.^[10] The Council’s statement on Best Practices suggests a five prong strategy: to explain plagiarism and develop clear policies; to improve the design and sequence of assignments; to attend to sources and the use of reading; to work on plagiarism responsibility; and to take appropriate disciplinary action.

The following studies investigated various forms of plagiarism pertaining to college students. For example, Klausman makes three distinctions between direct plagiarism, paraphrase plagiarism, and patchwork plagiarism.^[11] Lasarenko offers exercises to help students understand the differences between summarizing and paraphrasing practices, and how both can result in plagiarism if the original sources are not cited.^[12] Birnbaum and Gosciolo^[13] (cited in Kaltenbaugh^[14]) distinguish direct copying, rearranged copying, selective omission, copying selective words or phrases, paraphrasing, not citing a secondary source within a primary work, and making attribution unclear. In two separate studies with college students at St. John’s University, New York, Roig asked students to determine which of 10 rewritten versions were plagiarized.^[15] He found that 40–50% of the students did not identify plagiarized versions. Roig suggested that students in his tests were unclear as to what plagiarism meant.

The idea of “inadvertent plagiarism” or unconscious plagiarism has been examined in young and older adults.^[16] From the perspectives of memory as well as psychology and aging, experiments have established that older adults were more likely to plagiarize inadvertently than did younger adults. McCabe, Smith, and Parks conclude that the primary cause of the age differences in plagiarism is the nature of the retrieval processes involved

in monitoring for plagiarism errors, including age-related declines in recall of studied exemplars and/or to age-related declines in working memory.

WHAT DOES THE LITERATURE ON PLAGIARISM TELL US?

Literature on the topic of plagiarism is scattered, mostly descriptive, anecdotal, and has not as yet received a unique and deserving place in the scholarly literature it warrants. The reviewed literature asks important questions but the methodology used to study many of the questions is wanting in validity and applicability.

Plagiarism is a moral issue which is at the heart of the educational enterprise. It cuts across multiple disciplines, all sectors of the society, and hinges upon learning, teaching, levels of moral development, and applying ethical behavior in our everyday lives. This problem is reflected in the nature of literature that reports on plagiarism; it is spread out across library and information science, education, technology, social sciences, sciences, and ethics. How many English teachers read history or library-related literature? How many college instructors read literature especially targeted to secondary school teachers, technology coordinators, administrators, or to engineers and scientists? We have not made wide strides across disciplinary lines or between higher and secondary school education on plagiarism prevention. While the problems are basically the same, we see fragmentation along professions and educational status; professional conferences are designed around these lines, and literature follows the same structure. We need to learn much from one another, to share research results, evaluate models, and apply them in practice.

When this author searched ProQuest Platinum (thereafter ProQuest) database on the topic of plagiarism in peer-reviewed full-text articles, she retrieved the following distribution of results summarized in Table 1. It suggests a trend toward a significant increase in published articles on plagiarism since Internet has become widely available in various educational institutions. The numbers show rise of published literature at more than sevenfold in ProQuest Platinum database since the Web has become an ubiquitous and widely affordable information resource at all levels.

Plausible explanations are that: 1) plagiarism has started to receive the attention it deserves in the literature; 2) there are more cases of plagiarism detected, and with the advent of cyber-media in schools, colleges, and work places, more allegation cases are reported in the literature; and 3) it is easier to detect plagiarism as more electronic submissions are requested by publishing houses, and therefore it has become easier to compare texts on similarity strings and detect plagiarized contents.

Besides ProQuest and JSTOR, this author searched *Library and Information Science Abstracts*, Online

Computer Library Center (OCLC)'s *FirstSearch* databases, such as *ArticleFirst*, *PapersFirst*, *Library Literature*, and *Dissertation Abstracts Online*. The retrieved items are published in journals, newspapers, reports, dissertations, and conferences. In addition to the information obtained from database searches just described, this author reviewed published bibliographies. The Center for Teaching and Learning maintains compilation of articles from a variety of sources on plagiarism-related issues. Other bibliographies are in books, such as in Harris^[17] and in Marsh.^[18] For example, a brief content analysis of 154 entry bibliography on plagiarism demonstrates that the topic is largely fragmented and domain-centered with little or no attention given to the domains outside the scope of authors' own. Bill Marsh, an English language instructor, in his book titled *Plagiarism: Alchemy and Remedy in Higher Education*, covers literature from 1874 to 2004 with about 70% pieces published since 1992 from the perspectives of electronic media composition techniques, education, rhetoric, print history, and communication.

Previous editions of *Encyclopedia of Library and Information Science* (ELIS)^[19,20] contain articles under headings of copyright-related issues such as fair use and piracy. In volume 2, Jay Daily defines the word "piracy" as an "unauthorized publication of works," and taken to mean differently from plagiarism in that the "original author may be given credit for the intellectual content" p. 263.^[19] In the 1988 Supplement to ELIS (volume 43), W. Z. Nazri's article titled "Federal actions against plagiarism in research," reviews "policies and specific cases involving plagiarism in federally funded research" including such agencies as the Office of Research Integrity of the U.S. Public Health Service and the Office of Inspector General of the National Science Foundation.^[20] The article gives definitions of plagiarism as adopted by the research agencies, frequency of plagiarism allegations, process, findings, and actions taken against plagiarists.

The literature reviewed for this entry is primarily focused on plagiarism issues among secondary school students and college students.^[9,11,15,21,22] A subset of that literature is concerned with issues among professional school students.^[23–28] Articles cover scenarios of single case plagiarism-related issues in individual educational institutions, ranging from secondary schools, higher education institutions, research labs, professional schools such as nursing, business, engineering, and science. Though interesting, these reports cannot be generalized to populations outside a single case study or a

single school described in any given report. Other articles in newspapers, magazines, and search engine alerts continue to report sensational cases that involve paper mills, software companies, stories about prominent figures in journalism, writing composition, research, and academe.

The author examined literatures for effective pedagogical approaches that instructors can use to design specific academic integrity programs that would be appropriate for secondary schools and colleges. Since students at different levels of their cognitive development reason differently when presented with specific moral dilemmas,^[29] educators need to customize academic integrity programs to make them sensitive to and compatible with students' levels of moral reasoning.

HOW PREVALENT IS PLAGIARISM?

Under the "Extent of the Problem," Kibler reviews literature that demonstrates that various forms of academic dishonesty have been with us since ancient civilizations, and that academic dishonesty, for a variety of reasons, has increased.^[21] More recently, literature has shifted its attention from the student behavior toward a more robust approach to academic integrity taking into consideration a broader environment of teaching and learning.^[30]

In terms of K-12th grade educational level, the *Center for Academic Integrity* consortium of more than 300 institutions at Clemson University, South Carolina, publishes valuable reports such as "Smart & Good High Schools: Integrating Excellence and Ethics for Success in Schools, Work, and Beyond."^[31] Josephson Institute's "2008 Report Card on the Ethics of American Youth," reveals that young people are almost anonymous in saying that ethics and character are important on both a personal level and in business but they express very cynical attitudes about whether a person can be ethical and succeed.^[32] Based on a survey of 29,760 students in public and private high schools across the United States, the *Report* found that 64% cheated on a test within the past 12 months, up from 60% in 2006. There were no gender differences on the issue of cheating on exams. However, students attending independent schools reported the lowest rate (47%) compared to those attending religious schools (63%). The lowest cheating rate was reported in the Midwest (59%) compared to the Southeast (70%). Thirty-six percent of the surveyed students copied an Internet document to a classroom assignment within the past 12 months compared to 32.9% in 2006.

Working with a smaller set of secondary school children, an exploratory study examined students' understanding, their attitudes, and general practices toward cyberplagiarism.^[33] The article, based on a sample of availability, surveyed 37 high school juniors and framed questions in the context of information literacy standards and

respective performance indicators. The study used a self-reported paper-and-pencil questionnaire to obtain data on content knowledge (what students say they know), students' attitudes toward cyber-plagiarism-related issues (what students feel), and students' practices (what students are telling us they actually do). Among the interesting findings was the extent of difficulties students had with regard to giving credit to creators of nonbook resources. Examples included photographers, choreographers, and cartoon artists. Equally confused were the students with respect to attributing to computer code, information obtained through e-mail transcripts, and personal communication. To gauge the question, "Is the Google generation information literate?," a case study looked at information-seeking behaviors of 105 middle school students.^[34] The surveyed students are fluent with digital cameras, iPhones, Blackberries, Facebook, MySpace, YouTube, and Amazon's Kindle interfaces; their first best sources, regardless of the nature of inquiry, included search engines, (wiki)cyclopedias, books, and primary (digital) sources. Their perception was that 80% or more of everything that has been published is available on the Web. Other findings include problems with attribution, especially of digital resources, understanding what primary sources are, how to critically separate good sources from inappropriate or unreliable ones, and how to find those golden nuggets from the deluge of data. The surveyed students have both conceptual and mechanical problems in deciding when to give credit and how to do it properly; many come from elementary schools confused as to the differences between quoting and paraphrasing. More than 8 out of 10 surveyed students would give credit in order to "avoid plagiarism-related issues" (82%). Clearly, there is a gap between the surveyed students' understanding of the concepts of the ethical use of information and the belief that provided the basis for the newly created information literacy *Standards for the 21st-Century Learner*—that ethical behavior in communicating information is crucial.^[35]

There have been a number of studies of college students in the context of plagiarism-related questions. Roberts, Anderson, and Yanish found that in the self-reported 1997 surveys of 422 college students at a midsized 4 year public university, 91.7% reported that had engaged in at least one type of academic misconduct during the surveyed year.^[36] Virginia Polytechnic Institute reported that various forms of academic cheating have more than tripled, from 80 in 1995/1996 to 280 in 1997/1998. Virginia Tech is one among numerous campuses that has seen a rise of plagiarized information stolen from the Internet, e-mail, and other digital communication services. Ten years later, however, Virginia Tech has developed their Undergraduate Honor Code System which functions are to communicate the meaning and importance of intellectual honesty to all students of the University; to articulate and support the interest of the community in maintaining the highest standards of conduct in academic affairs; and to

identify, sanction, and educate those who fail to live up to the stated expectations of the university community with regard to these standards.^[37]

Authors from Harvard University and University of Illinois at Urbana-Champaign found that in their introductory political science course in the spring of 2000, about one out of eight papers seemed problematic.^[38] In the spring of 1999, a University Honor Council survey found that 54% of Penn students "considered copying homework to be cheating," and 61% of the students indicated that they would not "report a case of cheating to the Office of Student Conduct."^[39]

In the scientific world, several recent incidents reported that stellar scholars at two highly regarded research institutions (Bell Labs, and separately at the Lawrence Berkeley National Lab), faked data. In his article, "Peer trouble: How failsafe is our current system at ensuring the quality and integrity of research? Not very," says Crace.^[40] The author reports on a recent study by the University of Minnesota of 4000 researchers "that one in three scientists plagiarized, 22% handled data "carelessly" and 15% occasionally withheld unfavorable data." Most recently, Ben Martin, in his editorial article, details a case of a serial plagiarist, Hans Werner Gottinger (management/economy) who had been caught numerous times; each time he confronted the problem by moving to different research labs and academic institutions in the United States and Europe, and by apologizing, retracting his papers, and repeating all over again at his next affiliations.^[26] In an anonymous article, "Policing Integrity," scientific misconduct, especially plagiarism, has been discussed.^[41] Oversight organizations of the Office of Research Integrity at the Health Department, and by the Nation Science Foundation (NSF) in the United States are contrasted with those in Britain, France, Italy, and Germany. Sandler, an attorney at law, marshals examples of statutes from 14 states about sales of term papers; he gives detailed accounts of plagiarism by students, professors, and cases against commercial agencies that sell papers.^[42]

ATTITUDES OF FACULTY TOWARD ACADEMIC DISHONESTY

As we have seen above, the literature suggests some disturbing facts on the state of academic dishonesty in the United States, especially the growing prevalence of plagiarism. Other related research offers insight into the attitudes of faculty toward plagiarism. In his 1997 dissertation, Burke studied factors that influence faculty response to academic dishonesty at a multicampus, 2 year college. His "research investigated faculty: 1) perceptions of the extent of academic honesty; 2) perceptions of, and attitudes toward Academic Dishonesty Policy and policy implementation; 3) responses to academic dishonesty; 4) attitudes concerning values education; and 5) attitudes about responsibility for reducing academic dishonesty"

(p. 3).^[9] The study delineated perceptions, responses, and attitudes among faculty grouped by employment status, campus, seniority, and discipline. Seven hundred and forty two faculty members completed a 25-question survey. The results indicated that faculty do not perceive academic dishonesty to be a serious problem. Faculty believed themselves to be familiar with current policy and procedure, and are not concerned with policy implementation. The surveyed faculty members believe that they have a primary role in values education. Of the faculty surveyed, 86% have suspected, and 65% have been certain of, academic dishonesty in their classrooms. The majority of the surveyed members do not regularly follow institutional policy; most handle incidents of cheating and plagiarism on the individual basis. They believe that the responsibility for reducing academic dishonesty lies primarily with students and individual faculty. The fact that 86% of the studied faculty have suspected academic dishonesty in their classrooms, and did not perceive this to be a major problem, should be investigated further.

Marcoux's doctoral work studied college faculty's awareness level of the Kansas State University's honor code and cheating policies.^[43] The faculty's responses varied and indicated that they had not received training in how to handle cases of academic cheating.

Freedman^[44] reports his experience with preservice elementary school science teachers; some plagiarists were apologetic, others were offensive. He proposes prevention rather than detection as a new paradigm to combat plagiarism. For example, Freedman asks his student teachers to find an existing lesson plan, and creatively adapt for his or her students, language, and programs; another technique requires students to reflect on the relevancy of selected lessons with regard to diversity, assessments, and inquiry-based teaching. While we have no data on evaluation of the proposed program, it seems reasonable to assume that teachers will benefit in many ways to access information, critically evaluate source lesson plans, acknowledge the sources, and adapt to suit their needs.

Johnston's article reflects on a moral dilemma she dealt with relating to cheating that occurred during one of her unproctored exams in her Moral Development and Education course by some upper division students at Colgate University in New York.^[45] She decided to use that incident as a teaching challenge and "role-taking" technique. When Johnston confronted her class, she was alarmed with the range of students' responses. Some were surprised if no one cheated, some did not know how to deal with cheating if it occurred, many students rated cheating on a continuum, some viewed cheating as "refreshing the memory," others were bothered that students majoring in education in that particular class cheated. Students were equally divided about moral decision making as a group. Johnston's analysis of cheating takes her to search for causes of cheating behaviors beyond pressure and individual integrity. She writes, "it occurs because students do it if they won't 'get

caught' and being caught by their peers is not problematic" (p. 290). Ethical behavior is often assumed among professionals, such as teachers, managers, scientists, and other scholars. However, as Hall and Berardino point out, this set of skills unless taught cannot be taken for granted.^[25] Teaching professional behaviors (e.g., punctuality, honesty, cell phone usage, and appropriate appearance) is an important, complex, and underestimated area in general educational systems. It seems that there is a lack of alignment between offences and punishment, and lack of communication between administrators, faculty, parents, and students. Other problems are related to students' state of readiness to understand issues involved in academic dishonesty and plagiarism, and in relationships with peers, teachers, and as part of their educational climate as a whole.

CAN WE PREDICT ACADEMIC DISHONESTY?

The reviewed literature identified specific variables of learners in ethical uses of information.

Social Factors as Predictors of Academic Dishonesty

In a broader context, we sought to find societal indicators that strongly and positively correlate to academic dishonesty. Again, we turned to *The State of Americans: This Generation and the Next* to find possible answers to this question.^[46] There is evidence to support that nuclear family correlates positively and strongly with students' academic performance (GPA scores), cheating behavior, drug use, and teenagers' trust in others.

In competitive classrooms across the board, under parents' pressure to produce high grades, many students, including those from professional schools, have been found guilty of academic misconduct and plagiarism. Kibler divides his literature review into *Personal Characteristics of Cheaters* and *Situational Factors Involved in a Student's Decision Whether to Cheat*.^[21] Among the situational factors, important ones include unproctored tests, penalty systems, teaching styles (authoritarian style incites cheating, overly difficult tests, hopelessness, soft teachers), climate of the school, and "likely to get caught" (pp. 257–259). Schab writes that high school graduates cheat due to "fear of failure," because "parents demand and expect good grades" in order for their children to be admitted to top universities; other reasons given were that everyone cheats, and that teachers were "too soft on these issues" (p. 840).^[47]

Individual Differences as Predictors of Academic Dishonesty

In the study mentioned earlier, Roberts, Anderson, and Yanish examined the relationship between demographic

variables and academic dishonesty among undergraduates.^[36] A total of 422 students from 22 classes completed a 27-item self-reported survey that was designed to measure their involvement in 17 types of academic misconduct. The survey also obtained data on class standing, age, gender, GPA, and college major. Results revealed that being male and/or younger than 24 years of age were characteristics associated with greater involvement in academic misconduct. The authors did not find significant difference in self-reported academic misconduct between students and respective GPA scores.

In an earlier study, the authors used a questionnaire to obtain data on self-reported frequency of 21 cheating behaviors ($n = 943$) sophomores and juniors from 19 disciplines).^[48] This “first large-scale study of cheating carried out in the United Kingdom” (p. 238) calculated the frequency with which each reason was given for both cheating and for not cheating. Reasons given for cheating include time pressure, to get a higher grade, because everybody does it, to help a friend, and laziness. Students gave reasons for not cheating “because it is immoral,” “situation did not arise,” “it was unnecessary,” and “personal pride” (p. 233). The study found that men cheated more, that cheating declines with age, and that it occurs more frequently among science and technology majors than among other disciplines.

Pennycook writes about some of the complexities of text, ownership, memorization, and plagiarism.^[49] The author suggests that plagiarism needs to be understood in terms of relationships between text, memory, learning, literacy, and cultural differences.

Six hundred and ninety-eight college students from nine universities completed a survey on Internet plagiarism. A substantial minority of the surveyed students reported they used the Internet to copy and paste text into their own papers without giving credit to sources they used in their writings. Buranen in her piece, “But I wasn’t cheating: Plagiarism and cross-cultural mythology,” presents experiences with ESL (English as a Second Language) students and their writing problems and practices.^[50] In many cases, students lack a combination of vocabulary skills, factual knowledge, and bibliographic conventions. According to Buranen, cultural differences may also influence students’ attitudes toward “borrowing” and “ownership” of ideas or of text” (p. 66). Cultural perspective has been further explored by Dryden in the context of Japanese education (pp. 75–85).^[51]

Angélil-Carter writes about developing writing skills in general and not limited to non-English language students.^[52] She writes, “This is what is so difficult for the novice writer of academic discourse (or for any writer)—it is the control of the voices so that the authorial voice speaks through them. . .” (p. 35). Nearly 70 years earlier, Edwards wrote about “good and bad borrowing,” differences between imaginative and unimaginative borrowing, and those between a derivative artist and a thief.^[53]

COPING WITH PLAGIARISM

In his chapter on “The Moral Atmosphere of the School,” Kohlberg summarizes important findings by educational sociologists, such as Emile Durkheim, Philip Jackson, Robert Dreeben, and Edgar Friedenberg.^[53] Kohlberg introduces us to a concept of “hidden curriculum” in which characteristics of the crowds, the praise, and the authority are of major influences on the development of children. “After the family the school is the first social institution an individual must deal with, the place in which he learns to handle himself with strangers” (Friedenberg, *Coming of Age in America*, 1963, p. 149).^[53] Kohlberg’s research builds on that tradition and on the notions of Dewey and Piaget, and finds that the development of moral reasoning is sequential progression through distinct stages. Kohlberg believes that the role of the teacher is to translate moral ideology into a working social atmosphere in which students understand the meaning of the “hidden curriculum” based on the universal principle of justice underlining respect of all people. In this context, teachers have considerable flexibility to implement “hidden curriculum” within respective school cultures. Theories of ethical reasoning are in line of combating plagiarism through teaching, information literacy units on ethical use of information, and campus-wide honor code policies. Another line of coping with plagiarism has been through detection tools and adjudication of student plagiarism. These two perspectives are described next.

Ethical Reasoning

Granitz and Loewy studied theories of ethical reasoning that students invoke when they defend their plagiarism behavior.^[54] The researchers used a content analysis of written records of students formally charged with plagiarism. The authors classified case studies based on six types of reasoning students gave as justification for their academic misconduct. These were deontology, utilitarianism, rational self-interest, Machiavellianism, cultural relativism, or situational ethics. The authors found that students predominantly invoke deontology (41.8%), followed by situational ethics (19.9%) and Machiavellianism (18.4%). Under *deontology*, students typically justify their dishonest behavior by saying that they didn’t know what plagiarism was or that it was wrong. The *Machiavellianism* reasoning considers the act successful if they can get away with it without being caught. The *situational* plagiarism blames a given situation for dishonest activity (e.g., being late, being poor, inequity, stress). For each of the six reasoning theories underpinning plagiarism, Granitz and Loewy recommend prevention techniques: have honor code, teach proper citation techniques, act as a role model, and avoid standardized assignments. Based on responses obtained from 2200 students on 21 college campuses,

McCabe and Trevino concluded that schools with honor codes had fewer repeat offenders.^[55] This finding has policy implications, and honor codes have been widely practiced in numerous campuses.

Online Instruction

Among plagiarism prevention Web-based tutorials within information literacy units, Jackson assessed data from 2829 student quiz scores on their understanding of plagiarism.^[56] The study found that students have difficulties with paraphrasing, don't understand the concept of plagiarism, and mechanics of citing sources. The article concludes that online tutorials should be considered a part of a broader educational framework in the area of intellectual property and academic integrity.

Plagiarism Prevention Techniques

An approach taken in Harris's *Handbook*^[17] against plagiarism is to teach students about plagiarism-related issues rather than to assume that they know what plagiarism is. He uses anecdotes, cartoons, and plain language to demonstrate differences between plagiarism and copyright issues, good citing practices and careless note-taking techniques, differences between paraphrasing, summarizing, and copying sentences and paragraphs. An important section is directed toward explaining reasons why plagiarism is unethical, and the benefits of citing sources. McKenzie suggests specific ways in order to "prevent highway robbery in an electronic age:" distinguish between levels and types of research, give instruction to educators to go beyond "just factual" scavenger hunts and challenge students to use facts to explain, solve problems, and make decisions; go beyond "conventional thinking;" encourage students to "emphasize essential questions;" learn how to paraphrase, summarize, and cite the sources of ideas or information; use of color-coded text to differentiate between the ideas of others (black ink) and students' fresh ideas, reactions, or insights (green ink).^[57] Niels reports that the entire academic program at the Central Park East Secondary School (CPESS) in New York City is organized around the five main questions: Whose viewpoint is being described? What evidence is there? How is this connected to other things? What are the alternatives? How is this relevant? Niels develops an argument that in order to deal with various forms of cheating behavior, we need to look at contextual factors that influence cheating, which is moral education.^[58]

Brown and Howell, both with the University of St. Andrews, Scotland, studied the effectiveness of policy statements of plagiarism on students' behaviors.^[59] The study concluded that there was a positive influence between students who read carefully worded statements of plagiarism and respective academic behaviors.

Software Detection Programs

In their two 90-student sections in Introduction to Political Science course at the University of Illinois at Urbana-Champaign, Braumoeller and Gaines used assignment sheets with: 1) explicit written and verbal warnings not to plagiarize in one section; and 2) plagiarism detection software in another section.^[37] The investigators found that while verbal and written warnings not to plagiarize had a negligible effect on rates of plagiarism, plagiarism detection software proved to be successful in discouraging students to plagiarize. Policing plagiarism in any of the environments seems to be of mixed success.^[60] This author has long been in line with those who strongly feel that software tools such as turnitin and eve are at the end of plagiarism pipeline, and therefore limited. As Evans states, trust and student honesty remain central to a successful academic scholarship.^[59]

CONCLUSIONS

Plagiarism has always been known, although not adequately understood and reported, to teachers, administrators, behavioral psychologists, and sociologists. Literature has reported cases of plagiarism, under various names, including research misconduct, lack of academic integrity, academic dishonesty, misappropriation of intellectual property, and fabrication. This is not only a serious issue among students in secondary schools and colleges. It is rampant and on the increase among researchers, professors, and other professionals regardless of their age, discipline, seniority status, culture, and geographical region. Many have attributed its rise of epidemic proportions to a growing number of paper mills on the Web, "cut and paste" techniques, and educational culture as a whole; this has manifested itself through various ways in schools, such as instructors' inconsistent treatment and overall attitudes toward cheating, lack of plagiarism prevention strategies, uncertainty to interpret and apply honor codes, detect instances of plagiarism in print and electronic media, and customize teaching units on ethical use of information to meet students' uneven moral developmental capacities. In the higher education, plagiarism audits have been dealt with inconsistently and reported through peer review process, doctoral committee members, by individual readers, publishers, editors, and funding agencies. Much progress has been made about understanding of plagiarism and how to deal with at various levels of educational ladder. We need more effective pedagogical tools to engage students in real-life dilemmas at their levels of moral reasoning. We have illustrated paradigm shifts that have taken place between pre-Web and the Web era in Table 2.

Research is needed to study predictors that might suggest students' behavioral patterns at different phases of their reasoning development. Attention is also needed in

Table 2 Paradigm shifts in dealing with plagiarism

Paradigm shifts in plagiarism	Pre-Web era	The Web era
Medium and format	Piracy of mainly <i>printed texts</i>	Piracy of <i>multimedia</i>
Method of copying	<i>By hand</i> , purchase papers	" <i>Cut and paste</i> ," paper mills
Domain: discipline and level of educational institutions	<i>English</i> teachers mainly at <i>college</i> level	<i>Multiple disciplines</i> (e.g., library literature, science, and professional schools) at different levels including secondary schools
Combating plagiarism in educational domains	<i>Mechanical</i> techniques: template-based bibliographic citations; detect and punish; however, some authors write about plagiarism preventions in pre-Web era (e.g., Daniels ^[65] , Saalbach ^[66] , and Carroll ^[67])	<i>Conceptual</i> techniques: Focus on the <i>reasons</i> to give credit to sources; scenario-based discussion prior to mechanics (how to apply templates to specific cases)
Pedagogical approach as represented in Information Literacy Standards	Legalistic approach, need for educational approach (see, for example, Drum ^[68])	Intellectual property and digital rights management → Learning Standards. ^[35]

the areas of mapping research results to pedagogical experiences and specific subject (and interdisciplinary) authentic scenarios and lesson plans, diagnostic and assessment tools that instructors can customize for individual curricular needs.

FUTURE RESEARCH

Doctoral level work in the context of moral reasoning and development starting with seminal works by, for example, John Dewey,^[61] Jean Piaget,^[62] and Lawrence Kohlberg^[29] can advance our understanding and give us a conceptual framework around which to design research with specific questions in mind. Reporting beyond anecdotal stories would be useful in order to study trends of various segments in our society, reasons "plagiarism is on the rise," factors affecting these behaviors, as well as prevention strategies that might be considered and put in practice. In summary, plagiarism is not an isolated problem to any particular discipline.^[26,63,64] It is systemic issue of epidemic proportions requiring the entire educational community to mobilize, to study the problem from different angles, communicate findings, propose models, verify, and translate into best practices across the educational ladder.

Poland: Libraries and Archives

Jadwiga Woźniak-Kasperek

Institute of Information and Book Studies, University of Warsaw, Warsaw, Poland

Abstract

This entry discusses the role and status of Polish libraries and other information institutions during the two decades following the collapse of Communist rule in 1989. Although the focus is contemporary issues, a short historical overview is included. Special attention is paid to the National Library, its collections, activities (including the compiling of the national bibliography), and the Polona National Digital Library project. Other Polish digital libraries are also briefly described, as well as the first fully computerized union catalog called NUKAT. Major topics discussed include library legislation, public, school and research libraries, library networks, and professional education. There is also a brief section concerning archives and a briefer discussion of museums.

INTRODUCTION

Poland is a republic in Central Europe bordered by Germany to the west, Belarus and Ukraine to the east, the Czech Republic and Slovakia to the south, and Lithuania, Russia, and the Baltic Sea to the north. It has a population of 38,500,696 (July 2008 estimate) making it the sixth most populous country in the European Union, which it joined in 2004 (Fig. 1).

Historical Background

The history of Polish libraries began with the Christianization of the country in 966 and the adoption of Latin culture. Cracow's (Polish: Kraków) capitulary library inventories of 1101 and 1110 are the earliest book lists in Slavic Europe. In 1364 King Casimir the Great founded a university in Cracow, which was first called Cracow Academy. This institution was the second university to be established in Central Europe, after Prague (1348). From 1400 onward the library collections of individual colleges started to accumulate quickly. The most prestigious among the colleges was Collegium Maius, which had an important book collection by the sixteenth century, and therefore started to be acknowledged as the main university library. During its entire history, the university in Cracow played an important role in the history of book culture in Poland. The most important function of Polish libraries in the first period of their existence was book collecting, and sometimes book production (copying, illuminating, binding, etc.) Yet the social impact of the collections established at royal or ducal courts, or in religious institutions, was limited to a narrow elite.

The sixteenth century—a time of the Renaissance and the Reformation—has often been called the golden age of

Polish culture. This cultural flowering was stimulated by the spread of printing, and this in turn initiated a new phase of library development. Outstanding humanists, lay and church dignitaries, created their own private libraries; even wealthier burghers started to collect books. The library of King Sigismundus Augustus (d. 1572), which included over 4000 volumes, holds a prominent place among the Polish book repositories of the time. Later on, this extremely valuable collection was dispersed.

During the sixteenth century, Western influence stimulated a new type of library development in Poland: municipal libraries established by city councils. The Renaissance also fostered a deeper understanding and love of books, and elitist bibliophily flourished. Nonetheless the dominant trend was a pragmatic one. Most books purchased were primarily of utilitarian character, in the broadest meaning of the term: professional, intellectual, and ideological. School libraries also appeared during the sixteenth century after the arrival of the Jesuits in Poland in 1565.

The beginning of the seventeenth century is a distinct turning point in the history of Polish printing and librarianship. The Polish–Swedish wars (1601–1639 and 1655–1660) drastically diminished the holdings of Polish libraries. The wars not only brought about an end to some of the private collection (for example, that of the royal Vasa family) they also brought losses and instability to institutional libraries belonging to churches, monasteries, and schools.

The university library in Cracow also was changing during the seventeenth and eighteenth centuries. Even though the Collegium Maius Library was acknowledged as the main university library, separate collections of individual colleges still existed. However, during the eighteenth century, Hugo Kołłątaj (writer, politician, philosopher, and school reformer) initiated the process of

Fig. 1 Map of Poland.

Source: CIA World Factbook. <https://www.cia.gov/library/publications/the-world-factbook/geos/pl.html>.

bringing them together, which resulted in the present day Jagiellonian Library.

The eighteenth century brought chaos and the military defeats of the Saxon period (1697–1763) led to the partitioning of Poland among the neighboring powers of Russia, Prussia, and Austria (1772, 1793, 1795). These events ultimately led to the total annihilation of the Polish–Lithuanian Commonwealth. At the same time, the eighteenth century brought about the flourishing of Enlightenment and the reforms of the country during the reign of King Stanislas Augustus Poniatowski (notably the Constitution of May 3, 1791). The Enlightenment was the time when all types of libraries developed. Eighteenth-century ideology, science and teaching subjected all earlier concepts and ideas to criticism and revision by reason. Book repositories were an essential element in this process. The end of the eighteenth century saw a national uprising orchestrated by Tadeusz Kościuszko (1794), that led to the foundation of modern Polish society, interested in new forms and ideas in culture. School librarianship underwent substantial changes too. This intellectual ferment prevailed in spite of partitions during the subsequent period of national captivity.

Libraries and books played an important part of all those turbulent changes. The institution which impressed its mark on the history and character of Polish librarianship the most, was the Library of the Polish–Lithuanian Commonwealth, commonly referred to as the Załuski Library (in commemoration of the brothers Andrzej Stanisław and Józef Załuski, who founded it). That library

was also a school of professional librarianship. Its holdings brought together a large collection of unique value, abundant in rare prints and exceptional bibliophile specimens. On the basis of that collection, Józef Andrzej Załuski compiled, the nearly complete, multivolume national bibliography: *Bibliotheca Polona Magna Universalis*, the first national bibliography in Polish history. *Bibliotheca Polona Magna Universalis*, which remained in manuscript form, was annihilated alongside the other works of Załuski and the manuscript catalogs of the library in 1944, after the Warsaw Uprising. Only the partial, printed catalogs and bibliographies prepared by Jan Daniel Janocki, librarian, are still in existence.

The Załuski Library formed the foundations of the Polish National Bibliography and of the Polish National Library. The Załuski Library ceased to exist in 1795 when as a measure of repression, after the Kościuszko Uprising it was confiscated and transported to St. Petersburg, where it became part of the Imperial Public Library and several other Russian libraries. Some of its holdings were returned to Poland after the Riga Peace Treaty of 1921, only to be destroyed during World War II. Today, only individual books are in existence.

The most modern of Polish school libraries was the one of the Warsaw Collegium Nobilium (1765–1794). Throughout the country, truly novel solutions, even by international standards, as to managing school libraries were introduced by the National Commission of Education (1773–1794). It created a network of school libraries after the dissolution of the Jesuits' monasteries in 1773, reorganized two university libraries [in Cracow and in Wilno (currently, the capital city of Lithuania)], and set up district and province elementary school libraries. Hence, it can be summarized that the eighteenth century in Poland brought about important developments in librarianship, chief among which were the appearance of public libraries, organization of a network of school libraries, secularization, creation of the Library of the Collegium Nobilium, modernization of collections, cataloging and access, establishment of librarianship as a profession and recognition of its legal status, beginnings of library law, national bibliography, proliferation of bibliophiles, and collecting attitudes.

During the whole of the nineteenth century Poland was partitioned between its three neighbouring countries—Russia, Prussia, and Austria. This had a lasting negative impact on library development. But there were also a positive impact on book culture and libraries. For example, one can observe the development of collecting attitudes among the educated classes, chiefly in the form of bringing together all types of publications concerning Poland, with the intention of preserving Polish culture. The nineteenth century was also the time that works such as the *Bibliograficznych ksiąg dwoje* (1823–1826; Bibliographical Book Duo) by Joachim Lelewel were produced. This outstanding work includes the foundations of the

theory and methodology of the bibliography and its importance cannot be overestimated. Unfortunately it has never been translated into foreign languages.

In the part of Poland occupied by Austria, an impressive public library was opened in Lwów (1827) under the name of the Zakład Narodowy im. Ossolińskich—bibliotheca patria (Ossoliński National Institution—bibliotheca patria). In Prussian Poland, Count Edward Raczyński donated his family collection, chiefly from his Rogalin residence, to the nation. From 1868 Karol Estreicher Sr., author of the monumental national retrospective bibliography (*The Polish Bibliography*) and the reformer of Polish librarianship to the German model, worked on shaping the Jagiellonian Library in Cracow into a modern, European library.

Immediately after World War I, when Poland regained its independence, new libraries were established. The most important was the opening in Warsaw of the National Library (1928), under the direction of Stefan Demby (d. 1939). Some of the specialized libraries, which still exist, were organized in that time: the Library of the Central Statistical Office (1918), the Central Military Library (1919); the Library of Parliament (1919), and The Library of the Silesian Parliament in Katowice (1924). The number of libraries affiliated with higher education institutions rose during the interwar period from 10 to 32. In 1917 the Association of Polish Librarians came into being. Two important journals devoted to library issues started publication: *Przegląd Biblioteczny* (*Library Review*; since 1927) and *Bibliotekarz* (*The Librarian*; since 1919 primarily under the title: *Biuletyn Biblioteki Publicznej m. st. Warszawy*—*Bulletin of the Warsaw Public Library*). Designated libraries started receiving legal deposit copies from publishers.

World War II and the German occupation inflicted grave losses upon Polish cultural heritage in general and Polish libraries and books in particular. The losses are estimated at approximately 75% of all Polish library collections. Many librarians and professionals linked with books and literature were killed. As had happened in the past, during difficult times the activities of the Polish émigrés supplemented the book culture in Poland and were of great assistance.

Polish librarianship made considerable progress again after World War II. New libraries of all types were opened and functioned for the benefit of society. The establishment of the Polish Academy of Sciences in 1950 began a new period in Polish library history. It created new types of libraries that required a different kind of information services. The Library Act of April 9, 1968 provided the legal foundations for modern librarianship in Poland, including the specialization of libraries, interlibrary cooperation, and regulations concerning the licensing of librarians. The current binding act is The Library Act of June 27, 1997. Work is in progress to replace it due to its many shortcomings.

The Communist regime, in accord with its principles, took control over all book collections. During the whole postwar period, until 1989, preventive censorship was enforced by the Main Bureau for the Control of the Press, Publications and Performances in Warsaw, and by its delegations in individual provinces. Repressive censorship also existed. Nevertheless, from 1976 until 1990 (the official end of censorship in Poland) books were often issued outside the official system.

An unquestionable achievement during this period was the creation and upkeep of a network of numerous stable public libraries. Despite the fact that the administrative system changes in Poland did not always have a beneficial effect on the network, the country has provided the means (however modest they were) for the development of public libraries.

Research libraries were also developing due to industrialization and progress in research. This development however was hampered by the political isolation of Poland, problems with access to publications from outside of the Socialist Block and lack of access to technology.

Computerization of library and information processes began in the 1970s but progress was slow. In 1971 the appearance of further legislation, paved the way for the implementation of the National System of Scientific, Technical and Organizational Information SINTO. In practice, however, the system generally remained a concept, not a reality. Work on computerization of libraries was substantially accelerated two decades later. At present, the vast majority of Polish libraries, of all types, are computerized and their catalogs can be searched via the internet. Digital libraries and digitalization have become common practice and all services are directed for benefit of the public they serve. In the 1990s several major library buildings were constructed, among them the new facilities of the University Library in Warsaw (Fig. 2), which have already become an integral part of the largest Polish university and its capital city. In general Polish libraries have made significant progress and simultaneously have developed to better serve a new, democratic society (Fig. 3).

LIBRARIES

Library Legislation

The goals and areas of responsibility of different types of libraries are stipulated in the Library Act of June 27, 1997. The act introduces the concept of a national library network. In 2007 the network encompassed all public libraries (their participation is obligatory) and approximately 20 others, mainly those belonging to higher education institutions. One of the obstacles to the process of extending the network is the obligation imposed by Polish library law, which requires that a library willing to enter the network must apply through their founding bodies, (e.g., ministries,

Fig. 2 The University Library in Warsaw—outdoor sight.
Source: Courtesy of the University Library in Warsaw.

universities, local governments, and The Polish Academy of Science). Only the future will tell whether the national library network will be revived and what shape it will take.

During the transition from the communist system in Poland, which began in 1989, there have been many changes in the spheres of science, education, and culture

and in the field of law, with respect to libraries. The following acts were passed:

- An Act concerning organization and conduct of cultural activities (October 25, 1991; amended in 1994, 1996, and 1998).
- An Act concerning libraries (June 27, 1997).
- An Act concerning the changes of some acts defining the competences of the agencies of public administration with respect to changes in the administrative division of the country (July 24, 1998).
- Amendment of library law (July 27, 2001) which introduced the prohibition of combining libraries with other institutions.

With regards to these matters, the role of the Krajowa Rada Biblioteczna (National Library Council), an advisory body to the Ministry of Culture and National Heritage has been the key. It provides a meeting place for those in authority to learn more about public opinion.

Public Libraries

Public libraries in Poland are open to the general public and their resources are accessible free of charge. Should the need arise to charge the user for any kind of services, such as photocopying or scanning, the payment cannot exceed the costs of the service. Public libraries are simultaneously cultural institutions and information centers. They are organized in such a way as to facilitate easy access to library materials and information for the inhabitants of a given region. Public libraries in Poland are closely connected with and dependent on governmental and/or local administrations. Their activities are financed by the state or by local councils; in most cases they draw upon both sources simultaneously.

Fig. 3 The University Library in Warsaw—interior.
Source: Courtesy of the University Library in Warsaw.

As a result of such close ties with the administration, each change in the administrative structure of the country requires respective changes in the public library network. The last reform of the administrative division of Poland in 1999 introduced a three level system. The number of provinces (Polish: *województwo*) were reduced from 49 to 16, which were then broken down into districts (Polish: *powiat*; previously nonexistent as an administrative unit), and then each district was divided into councils (Polish: *gmina*—the smallest territorial unit). The current network of public libraries therefore consists of three levels reflecting the territorial division of the country. The lowest level is the level of council or local libraries. Each council is required to organize and support at least one public library with an appropriate number of branches and library outlets. The district is also required to organize and provide for at least one district public library, while the self-governing authorities of a province are obliged to organize and support at least one provincial public library. Professional guidance for all public libraries is the responsibility of the National Library.

In 1989 there were 10,313 public libraries, 3342 of which were located urban areas, and 6971 in rural areas. In 2007 there were 8489 libraries (2871 urban and 5618 rural). The decline in total numbers equals about 17%. On occasion small libraries are closed and their responsibilities are taken over by larger libraries. In some cases the reasons for dissolution of a library are cost savings. There are eighteen provincial libraries (two of the provinces have two provincial public libraries each). In 2008 due to the importance of their holdings, their activities and the qualifications of their staff, 12 provincial public libraries were awarded the status of public research libraries.

The number of registered readers is slowly but steadily rising. In 2007 about 6.7 million readers (commonly known as borrowers) were registered, most of them in urban areas. (For context, the total number of the Polish citizens is about 38.5 million). Looking at the statistics of the age of users of public libraries, we find that the largest group consists of those aged 19 or younger and these school age users make up almost half of the total. Persons 60 years of age or older represent the smallest group of library users. A review of readers' professions demonstrated that farmers are the least interested in public libraries (0.9% of the total).

A section for children and young adults (below 15 years old), can be found within public libraries; sometimes there are also separate collections for children. In urban areas there are some branch libraries especially for children and young adults. Some public libraries function as a part of another institution, such as a school (as joint public/school library) or a cultural center. These libraries do not have independent legal status because they are an integral part of the parent institution. In 2006, there were 2002 public libraries functioning within the structures of other institutions, including 250 joint public/school libraries.

From the point of view of the average person, public libraries are the most important type of libraries in Poland because they are legally mandated to be open to everybody without regard to his/her nationality, place of residence, educational status, or social background. Public libraries respond to the needs of the largest groups of users, thus forming an image of "the library" in most minds.

One can follow the most recent developments thanks to the bulletin *Public Libraries in Figures*, an invaluable publication to be found on the Internet (http://www.bn.org.pl/doc/bpwl_2006_pl.pdf), although the latest issue shows the data from 2006. National statistics that include libraries, museums, archives, etc. are available on the Internet on the Web page of the Central Statistical Office: http://www.stat.gov.pl/gus/45_737_PLK_HTML.htm The current list of libraries in Poland is available on the Internet <http://www.ebib.info/biblioteki>.

School Libraries

The activities of public libraries are complemented by school libraries. School libraries are the most numerous type of library; they are administered by the Ministry of Education. Every school in Poland is obligated to have a library, often called a media center. Their holdings consist of 156 million volumes; 151.8 million of these volumes are in schools for children and young adults, i.e., 20 million volumes more than in the public libraries network. This gives an average of 22 books for every student (in schools for children and young adults: 24) and for every school an average of 3907 volumes (in schools for children and young adults: 4577). Through their efforts in promoting reading and the use of other media, and through offering training in information literacy skills, school libraries play a key role in the preparation of future readers, media users and information seekers. School librarians in Poland enjoy the status of teachers and the title of "teacher-librarian." Other teachers are assisted by the librarians in their daily teaching work, in continual training, development and upgrading of their own skills and knowledge, and in introducing new forms and methods of teaching. School libraries also cooperate with parents, school staff, and other libraries.

RESEARCH LIBRARIES

Research libraries hold an important place in the Polish library system. Among these we distinguish the National Library, the libraries of the Polish Academy of Sciences, libraries of research and development units, and other libraries which support research and conduct research activities themselves, like those of higher education institutions. A library receives research library status on the basis of the character of its holdings, types of users served,

its activities, and the qualifications of its staff. In 1999 there were 1209 research libraries; this figure includes: the National Library; 981 libraries in higher education institutions; 98 libraries in research units of the Polish Academy of Sciences; 92 branch research and development units, and 9 public libraries.

In 2005 there were 1219 research libraries, which included 1 National Library, 1005 higher education institutions, 82 research units of the Polish Academy of Sciences, 89 branch research and development units, and 42 others, including 12 public research libraries.

One of the largest and most famous research libraries in Poland is the *Jagiellonian Library* (Polish: *Biblioteka Jagiellońska*, commonly known as *Jagiellonka*). Already in 1364 the Jagiellonian Library was considered the main library for the entire university. During the partition of Poland, the library continued to grow thanks to the efforts of such people as Jerzy Samuel Bandtkie, and Karol Estreicher Sr. Its collections were made public in 1812. In 1932, the Library was granted legal deposit status and obtained the right to receive a copy of every book printed in Poland by a Polish publisher. It has a large collection of medieval manuscripts, among them is the famous *De Revolutionibus orbium coelestium* by Copernicus. In 2007 the Library holdings were about 6.3 million volumes and on average 650,000 people visit the Library each year.

The Jagiellonian Library together with the Medical College Library and the departmental and chair libraries make up the library-information system of the Jagiellonian University. Thanks to its importance, its extensive collection of Polish publications and staff qualifications, the Jagiellonian Library is known as another national library. Currently, the Library collects and archives all Polish publications printed in Poland and abroad. The Library also collects foreign scholarly literature in fields related to the University's areas of research and coursework. Priorities include cultural studies, linguistics, literary studies, art, and religious studies. In the 1990s several priceless books (including Galileo, Johannes Kepler, Basilius Bessarion) were stolen from the library, presumably in order to be sold outside Poland. Some of them were recovered from an auction in one of the German auction houses.

The largest group among research libraries consists of the libraries of higher education institutions. These are organized in the form of an academic library network, which includes: the main library, libraries of individual faculties, institutes, chairs, centres, etc. The holdings of the main library cover all the fields of knowledge studied at the institution as opposed to the other libraries of the school's network, which are specialized.

There are also research libraries in nongovernmental institutions of higher education. In 2007 there were slightly more than 300 such institutions, but only one-third of them had a library.

Many of the research libraries cooperate to create a union catalog called NUKAT (Polish: *Narodowy Uniwersalny*

Katalog Centralny—National Universal Union Catalog; <http://www.nukat.edu.pl>). NUKAT is managed by the NUKAT Centrum which is an organizational unit of the University Library in Warsaw. The objectives of NUKAT are

1. Furnishing information concerning documents and their location.
2. Allowing for copying by local catalogs of bibliographic and authority records.
3. Acceleration of the cataloging efforts in individual libraries.

NUKAT is a catalog with a single, extensive central database of bibliographic and authority records. In mid-February 2009 the NUKAT database contained 1,231,492 bib records (almost 52,000 of which were for periodicals) and nearly 2,555,873 authority records (both name and subject headings). Over 900 librarians, employed in 60 libraries (chiefly in institutions of higher education), cooperate in the ongoing creation of NUKAT. Since 2005 this body had also included the National Library. However as of August 1, 2007 the National Library withdrew from the project. NUKAT primarily contains bibliographic records of recently acquired materials (since July 2002) of the cooperating libraries; in addition there are a certain, still growing, number of records which are the effect of retroconversion. Since 2006 NUKAT cooperates with OCLC. However, if one is looking for a document issued prior to 2002, it is better to use the search engine *KaRo* (<http://www.karo.umk.pl>).

Since 1992 some of the research libraries also cooperated on creating the subject headings system KABA, which is a universal system, with a relatively large vocabulary. Initially it was supposed to be compatible with the three subject headings systems used internationally: the American Library of Congress Subject Headings, the French RAMEAU, and the Canadian RVM. From 2006 the requirement of compatibility started to be treated less seriously. There are 22 libraries creating the KABA system, which was being implemented by a 30 additional libraries. In mid-February 2009, the KABA authority files (<http://www.nukat.edu.pl/nukat/pl/kaba.phtml?sm=5&poz=3&id=73>), which have never had a hard copy version, contained about 265,000 records for topical headings and about 1,126,000 records for heading-subdivision combinations.

The National Library

The National Library – Polish: *Biblioteka Narodowa* (<http://www.bn.org.pl>). At present, the National Library (Figs. 4 and 5) is under the authority of the Ministry of Culture and National Heritage. It is regulated by The Act concerning libraries, and by the Statute of the National Library, issued by ordinance No. 4 of the Minister of Culture and National

Fig. 4 The National Library in Warsaw—outdoor sight.

Source: Courtesy of the National Library in Warsaw.

Heritage (July 6, 2000). The above-mentioned legislation stipulates that the National Library is the central book repository of the country and one of the main cultural institutions of the nation. The National Library is responsible for conducting library, bibliographical, research, informational, conservational, advisory, editorial, and service activities. In particular, it is responsible for

1. Collecting, cataloging, informing, and preserving library materials, produced in Poland, and those published outside the country, if they are related to Poland.
2. Preparation and publishing of the national bibliography.
3. Conducting research in the field of librarianship, book, and related sciences.

Fig. 5 The National Library in Warsaw—interior.

4. Improving the functioning of libraries in Poland and Polish libraries outside of Poland.
5. Administering the centers responsible for assigning ISBN, ISSN, and ISMN.

The National Library collects manuscripts, old prints released by Polish publishers, contemporary publications, graphical, audiovisual, and electronic documents, as well as Polish publications issued outside of Poland, and foreign publications concerning Poland.

The initial basis for the creation of a complete archive of national publications is the law promulgated in 1927, by which the National Library received a legal deposit copy of all documents issued in Poland. Under current law The National Library receives two copies of every book, periodical, newspaper, musical notation, atlas, Brail publication, musical recording, audiovisual document, and electronic materials, leaflets, and gray literature. Currently work is in progress to take over the collections of the National Film Repository in Warsaw. As a consequence of this, the National Library will also receive a copy of every cinema and television production. Each year the National Library receives between 140,000 and 170,000 documents of various types, 75% of which belong to the category of legal deposit copies. The remainder are purchased, received as a bequest, or obtained through exchange programs. Through purchasing old works pertaining to national heritage, which appear on the antiquarian market, the library is rebuilding its former collections that were destroyed during times of war. All the Polish publications and valuable foreign items constitute a National Library Archive, and are therefore under additional protection. All Polish printed work and those which are related to Poland are gathered in at least two copies, one of which, listed as "A"-type copy, is accessible to the reader only in exceptional cases and exclusively in the reading rooms. The "A"-type objects form the archival, specially protected, holdings of the National Library.

The National Library is in possession of the oldest specimens of writing in the Polish language: the *Świętokrzyskie Sermons* (mid-fourteenth century), *St.-Florian Psalter* (Fig. 6) (late-fourteenth century), and the *Przemyskie Meditations* (fifteenth century). Among the more valuable manuscripts that represent the European literary heritage are

- The *Braniewo New Testament* (late-eighth to the early ninth centuries).
- The *Evangelary of Anastasia* with a silver, binding adorned with gold plate (twelfth century).
- The *Wilanów Psalter* (ca. mid-thirteenth century).
- The *Roman de la Rose*, fourteenth century.
- The *Calendarium Parisiense*, fourteenth century.
- The *Revelationes sanctae Brigittae* fourteenth century.
- The *Legenda aurea* (ca. 1480).
- The *Cosmographia* (1467)—an early copy of Ptolemy's Geography.

(cf. *More Precious than Gold*—http://www.bn.org.pl/doc/nzd_eng.pdf).

The materials in the National Library are of special interest to the historians of the Napoleonic era and of the history of the November Uprising (1830–1831), for art historians and for those working on the history of the Polish peasantry at the turn of the nineteenth and twentieth centuries, as well as for those interested in the history of the Polish socialists. The collection of over 10,000 volumes that belonged to the Schaffgotsch family of Cieplice, has substantially supplemented the Silesian materials. The library of the freemason lodge B'nei Brith, which was dissolved prior to World War II contributed numerous (2600) volumes of freemason publications. Philologists and historians of literature are particularly interested in those books, which came from collections belonging to Polish writers and bibliophiles. The collection of Polish scientific and technical literature, in particular with respect to older works, is less comprehensive than in other fields.

There are numerous periodicals from the early nineteenth century. The same applies to the January Uprising (1863–1865), with the caveat that this collection is supplemented by an extremely valuable set of periodicals, circulated illegally during the years 1861–1864 and a collection of émigré periodicals of the nineteenth century in general. There are also rare complete sets of nineteenth

century socialist publications, as well as agricultural periodicals of the same period and a formidable collection of calendars, taken over from the former Krasieński Family Library.

In spite of the gaps—the results of war losses—there is a fairly complete set of Polish periodicals from the interwar period, in particular those issued during the years 1927–1939. The collection of World War II conspiratorial periodicals ranks among the most extensive in the country. In addition, the National Library is in possession of the largest collection of microforms in Poland, which at the end of 2005 numbered nearly 242,000 units. Within this collection are 2500 units of unified sets of Polish periodicals that are of special value, encompassing materials beginning with seventeenth century special issues through to twentieth century journals. Single existing copies of these periodical issues were found in various collections and microfilmed, thus providing a full run and enabling wider access and scholarly use. Among the collections of ephemera, one can find leaflets dating back from 1801 to 1930 (e.g., parliamentary speeches, military orders, tsarist proclamations); from the November Uprising of 1830–1831; the Cracow Revolution of 1846; the Spring of Nations (1848); the January Uprising of 1863–1865 (proclamations, circulars, and manifestos of the National Government), and from World War I. There is an abundance of materials from World War II: the September Campaign in Poland (1939) and the German occupation. Finally, there are numerous valuable and rare posters.

By the end of 2007, the National Library contained more than 7 million items;

5,795,710 belonging to the main collection

- 2,496,480 volumes of books issued after 1801.
- 869,200 volumes of periodicals issued after 1801.
- 2,202,259 items such leaflets, grey literature, etc.
- 215,157 items of bibliological (book studies) special collections.
- 12,614 electronic documents.

1,385,934 items from special collections

- 26,810 manuscripts.
- 161,879 volumes of old prints.
- 119,257 units of printed musical notations.
- 106,935 units of musical and audiovisual units.
- 482,769 units of iconographical documents.
- 119,058 cartographical units.
- 266,993 microforms.

In 2002, with preservation in mind, as well as to create wider access and in accord with global trends, the National Library started to digitize its collections. In January 2003 a special agreement was signed with the University Library in Warsaw, aimed at creating a Digital Collection of Polish Periodicals. This collection of nineteenth century Polish periodicals is being created on the

basis of the microfilms made in the University Library. On October 11, 2006, with both library and Internet users in mind, the National Library launched the Polonal National Digital Library project (Polish: *cyfrowa Biblioteka Narodowa Polona*, cBN Polona; <http://www.polona.pl/dlibra>). The admission of Poland to the European Union in 2004 opened new areas of research and information activity. The National Library, as one of the ten national libraries of the new member states, participates in the TEL-ME-MOR project, aimed at unifying the access to the electronic holdings of the European national libraries and library services. As a result it became a partner of The European Library (TEL), and the holdings of the Polish National Library can be researched through the TEL portal.

NATIONAL BIBLIOGRAPHY

The current Polish national bibliography registers all documents published in Poland, notwithstanding their language or the nationality of the authors. It also registers documents published outside Poland, but related to her by subject matter, language, or the origins of the author. The aim is to provide as much as possible, a complete picture of the publishing production of the nation and the country. The current Polish national bibliography consists of four parts, all of which are prepared by the staff of the Bibliographical Institute of the National Library:

1. *Przewodnik Bibliograficzny* (Bibliographical Guide).
2. *Bibliografia Wydawnictw Ciągłych* (Bibliography of Periodicals).
3. *Bibliografia Zawartości Czasopism* (Bibliography of the Contents of Periodicals).
4. *Polonica Zagraniczne. Bibliografia* (Polonica Published Outside Poland: A Bibliography).

Przewodnik Bibliograficzny is a continuation of the interwar *Urzędowy Wykaz Druków wydawanych w Rzeczypospolitej Polskiej* (Official List of Printed Matter Published in the Republic of Poland), which was revived in 1946. At first it appeared irregularly, but since 1948 it has been published weekly. It is based primarily on the legal, signal copies sent to the National Library by the publishers. According to internationally acknowledged guidelines a national bibliography is to register books and the first issues of periodicals. *Przewodnik Bibliograficzny* registers also cartographical documents (maps and atlases, but not contour maps), musical prints (scores, songbooks, musical notations), graphics (but without single page prints), conference materials notwithstanding the number of copies issued, nor the physical form (e.g., bound folder), scholarly theses, notwithstanding their editorial form and destination, as well as bibliographical lists and Braille editions. It is not a complete bibliography. Iconographical documents are not included, neither are

sound recordings (since 1990 they are registered in the database called The bibliography of sound recordings), nor gray literature, while electronic documents have only been registered since 2001 (Bibliography of Electronic Documents; a supplement to the *Przewodnik Bibliograficzny*). Each year, approximately 25,000 bibliographic entries are registered. It is estimated that about 15% of the books and other materials issued in Poland are not registered in the bibliography due to the fact that the publishers fail to send in the legal deposit copies to the National Library. Starting in 1986, *Przewodnik Bibliograficzny*, has also been available in an electronic form, through the home page of the National Library. *Przewodnik Bibliograficzny* has a bimonthly supplement, which has appeared since 1976, registers new and suspended periodicals as well as title changes. During recent years it has registered about 1300 titles of periodicals.

Bibliografia Wydawnictw Ciągłych until 1981 appeared under the title: *Bibliografia Czasopism i Wydawnictw Zbiorowych* (Bibliography of Periodicals and Collective Editions); It is currently an annual publication that registers periodicals appearing in Poland. This bibliography registers approximately 5000 titles every year and has appeared regularly since 1996. Retrospective materials, which did not appear in print as current yearly volumes, are accumulated and prepared for publication as single volumes covering 5 years.

Bibliografia Zawartości Czasopism is a monthly publication that has appeared since 1947. It registers approximately 55,000 bibliographic units, mainly articles, each year deriving from over 1300 periodicals (chiefly scholarly). It covers all subject matter, although some of the topics (e.g., medicine, agriculture, military) are very sparsely represented, due to the existence of appropriate specialized bibliographies. Since 1996 this bibliography has also been available on CD ROM, and since 2005 it has been published exclusively in an online version.

Polonica Zagraniczne. Bibliografia is published annually and has appeared independently since 1956. Initially foreign polonica was registered together with the current bibliography of books. At present this bibliography registers about 2400 bibliographic descriptions every year, half of which are taken from 30 foreign national bibliographies and databases. It encompasses books, musical notations, maps, individual literary pieces published in collective publications and larger fragments of book publications in the Polish language, by Poles, or related to Poland by subject matter.

Apart from those mentioned above, a number of specialized bibliographies appear regularly:

- *Bibliografia Filozofii Polskiej* (Bibliography of the Polish Philosophy).
- *Polska Bibliografia Lekarska* (Polish Medical Bibliography).

- *Polska Bibliografia Literacka* (Polish Literary Bibliography).
- *Polska Bibliografia Wojskowa* (Polish Military Bibliography).
- *Polska Bibliografia Prawnicza* (Polish Legal Bibliography).
- *Polska Bibliografia Ekonomiczna* (Polish Economical Bibliography).
- *Polska Bibliografia Bibliologiczna* (Polish Bibliography of Library Science).

There are also numerous retrospective bibliographies, like the *Bibliografia polska* (The Polish Bibliography) initiated in 1870 by Karol Estreicher, Sr. and continued by his son Stanisław, and then by his grandson Karol Jr.; *Bibliografia historii polskiej* (Bibliography of Polish History) by Ludwik Finkel; *Literatura polska od początków do powstania styczniowego* (Polish Literature from the Beginnings to the January Uprising) by Gabriel Korbut (the second edition brought it chronologically until World War I); *Bibliografia literatury polskiej: "Nowy Korbut"* (Bibliography of Polish Literature: "The New Korbut").

All these bibliographies, despite the extensive expertise and precision of their compilers, usually still have one common weakness—they have no online version.

Digital Libraries

The first digital library in Poland, the Polska Biblioteka Internetowa (<http://www.pbi.edu.pl>), was unsophisticated from a technological standpoint, usually employing simple html Web sites with links to individual publications. As the digital libraries grew in size, they were supplied with search engines and metadata systems. They are orientated toward scanning and making available the generally recognized canon of culture (literary classics, historical heritage) no longer protected by copyright law. A major breakthrough came with the advent of the dLibra software (original Polish product). Its first implementation was the Wielkopolska Biblioteka Cyfrowa (2002). In mid-February 2009 the number of dLibra libraries exceeded 30.

There is no doubt that the most important implementation of dLibra is Polona by the National Library. The objective of the project is providing free of charge broad, general access to digital holdings. The unique character of the collections of the National Library was the chief factor considered in working through the guidelines for Polona. The highest priorities for digitization were the most valuable holdings, such as rare manuscripts, old prints, first editions of great works of Polish literature, and the conspiratorial World War II documents—all of which are seldom displayed in public. Such documents are no longer protected by copyright law. These publications are described using the Dublin Core Metadata Set. It was decided that the documents digitized and published in

Polona will not receive an independent bibliographic and library registration, therefore they will not be treated as separate entries in the catalog of the National Library. Exceptions to this rule will be made for documents enhanced in some way with respect to the original, e.g., created from selected fragments of the original, or compiled of several original documents. In such cases they will be considered as new publications. Full-time work on the creation of Polona commenced in July 2006. By the end of January 2009 the library numbered almost 16,000 units.

Over the last few years global tendencies in digital libraries have pointed to the centralization of smaller projects and the creation of great national or even international virtual libraries. Europe has the European Library (TEL) and the European Digital Library (EDL). Do we see the same tendencies in Poland? The network of digital libraries, which operates in Poland now, demonstrates that the collections available on the Internet are strongly regionalized. Should this process be assisted and preserved? It is hard to answer.

In the context of digitalization it is worthy of mention that in Poland there is only one periodical devoted to library issues published exclusively in electronic form: the *Biuletyn EBIB*, appearing in monthly intervals since April 1999. Each issue has a thematic character dealing with current matters and a different editor. This journal is an element of a wider Internet service for librarians—the electronic platform of the Association of Polish Librarians (<http://ebib.oss.wroc.pl>).

Professional Education and Training of Librarians

In contemporary Polish, the term “librarian” means a qualified employee of a library. The qualifications in question encompass either a diploma in library and information science from a higher education institution or higher education in another field and a postgraduate course in library and information science. In Poland, one still finds library personnel with professional training at the secondary level, but this group is constantly diminishing in numbers. There is also another category of library staff, librarians of higher professional status (commissioned librarians and commissioned specialists in documentation and information science), who are research workers. To achieve commissioned status one is required to have a degree, have an appropriate length of employment in libraries or information centers, publish scholarly works, attend conferences, have certified knowledge of at least one foreign language, and pass an exam before a state commission authorized by the Minister of Science and Higher Education.

The first chair in library science, to train librarians, was established at the Humanities Faculty of the University of Łódź in 1946; it was headed by Jan Muszkowski. Next came the Chair of Library Science opened by Aleksander Birkenmajer within the Philological Faculty of the

University of Warsaw (1951) and a similar institution supervised by Karol Głombiowski at the Philological Faculty of the University of Wrocław (1956). In 2008 there were 13 units in Poland, which offer programs in library and information science (University of Warsaw, University of Wrocław, Jagiellonian University in Cracow, Silesian University in Katowice, Marie Curie-Skłodowska University in Lublin, Białystok University, Szczecin University, Adam Mickiewicz University in Poznań, Nicholas Copernicus University in Toruń, University of Warmia and Mazury in Olsztyn, Gdańsk University, University of Łódź, King Casimir the Great University in Bydgoszcz, Pedagogical University in Cracow, and Świętokrzyska Academy in Kielce). Training is offered in the form of standard MLIS studies, consisting of two levels (a 3-year BLIS and a 2-year MLIS), both regular and part-time (extramural) studies. Post-master courses for university graduates in other fields wishing to pursue a library career are also available. Some of the aforementioned university centers, e.g., Institute of Information and Book Studies of the University of Warsaw, also offer post-master PhD studies. The quality of training is overseen by an independent interuniversity commission and a state commission (Państwowa Komisja Akredytacyjna—State Commission for Accreditation) authorized by the Ministry of Science and Higher Education.

The largest Polish library school is the Institute of Information and Book Studies of the University of Warsaw. In 1999 the 5-year masters program was divided into two independent cycles: 3-year BLIS and 2-year MLIS studies. Moreover, the Institute runs four post-master professional programs and doctoral studies. In 2007, approximately 1500 students, including approximately 350 full-time, 850 extramural, and 300 students in postgraduate studies attended the Institute. The Institute employs 38 full-time and 3 part-time research and didactic staff, including 16 full professors. (Fig. 7)

Organizations Supporting the Activities of Libraries and Librarians

There are several organizations that support librarians and libraries, including

- Stowarzyszenie Bibliotekarzy Polskich (Association of Polish Librarians).
- Polskie Towarzystwo Informacji Naukowej (Polish Society of Scientific Information).
- Polskie Towarzystwo Bibliologiczne (Polish Bibliological Society).
- Konferencja Dyrektorów Bibliotek Szkół Wyższych (Conference of the Directors of Higher Education Libraries).
- Towarzystwo Nauczycieli Bibliotekarzy Szkół Polskich (Polish Schoolteachers–Librarians Society).

Fig. 7 The Institute of Information and Book Studies of the University of Warsaw—logo.

Source: Courtesy of the Institute of Information and Book Studies of the University of Warsaw.

The Association of Polish Librarians is the largest and the most important among these organizations and was established in 1917. It brings together over 9000 members representing various types of libraries, although most members are from public libraries. Members of the Association can join task teams which are dedicated to particular issues of library theory and practice. Among the most important of these 16 task teams are the following: the Subject Cataloging and Classification Commission, the Automation Commission, the Private Higher School Libraries Section, the Regional Bibliography Team. The Association publishes five journals devoted to library and information science of national character. These are: *Bibliotekarz* (*The Librarian*, a monthly published since 1919 in cooperation with The Warsaw Public Library); *Przegląd Biblioteczny* (*Library Review*, a quarterly published since 1927); *Poradnik Bibliotekarza* (*Librarians' Guide*, a monthly published since 1949); *Zagadnienia Informacji Naukowej* (*Journal of Information Science*, published twice a year since 1963 in cooperation with the Institute of Information and Book Studies, University of Warsaw), *Biuletyn Zarządu Głównego Stowarzyszenia Bibliotekarzy Polskich* (a quarterly published since 1993). In all, about 40 library and information science periodicals of scholarly, popular, and professional character appear in Poland. The Association of Polish Librarians also has a publishing office, which is especially known for the series *Science-Didactics-Practice*.

In Poland libraries themselves are members of a group of cultural institutions. Of special interest are: the Book

Institute (<http://www.instytutksiazki.pl>), National Film Library (<http://www.fn.org.pl>), and the Polish Audiovisual Publishers (<http://www.pwa.gov.pl>).

MUSEUMS

The first museum in Poland was established by Duchess Izabela Czartoryska in 1801. At the end of 2007 there were 720 museums and nearly 300 art galleries in Poland, and among one can find the Museum of Children's Literature, a branch of The Warsaw Public Library (The Central Library of Mazovian Province) which was opened in 1938. Its collections encompassed 42,000 volumes of books and periodicals: Polish fiction for children and young adults, works of popular science (excluding school textbooks), periodicals for children, works on the theory of children's literature, biographies, bibliographies, and dictionaries. Literary classics and books bestowed by acknowledged international institutions are among the foreign literature found there. The foreign language section forms approximately 30% of the holdings. In accord with its name the Museum collects books of antiquarian value. It possesses numerous rare volumes published prior to 1900. The Museum is also conducting publishing activities, by issuing a new volume of the *Bibliografia z zakresu historii i krytyki literatury dla dzieci, bibliotekarstwa i czytelnictwa dziecięcego* (*Bibliography of history and critics of children literature, librarianship, and readership*) every year.

ARCHIVES

State archives in Poland are supervised by the General Director of State Archives, who in turn is answerable to the Minister of Culture and National Heritage. The General Director controls the state archives through his Head Office of State Archives (Polish: Naczelna Dyrekcja Archiwów Państwowych; <http://www.archiwa.gov.pl>). The main responsibilities of this office are the supervision and protection of the state archival holdings. In 2007, the archival network in Poland included: 30 state archives, 48 regional branches and 4 affiliated units of state archives, 3 central archives (Central Archives of Historical Records, Central Archives of New Records, National Digital Archives) and the State Archives of Personal and Payment Documentation. These repositories gather materials produced by local and central state institutions, law courts, self-governing administrations (including acts of town authorities), commercial and manufacturing organizations, family archives, landed estates, private persons, and regional institutions. Most of the materials kept in archives come from the nineteenth and twentieth centuries; however, in some cases charters can date as far

back as the Middle Ages. It is perhaps worth mentioning, that during the communist regime, there were no archives for local governmental institutions in Poland (or at least that is what was said). Archives for local government institutions, officially came into existence only after 1989.

In addition to those mentioned above, there are also other types of archives:

1. Specialized archives (11), which are responsible to respective ministries (e.g., the Archives of the Ministry of Foreign Affairs; Central Military Archives; Archives of the Parliament) and collect documents produced by those ministries and their organizational units.
2. Archives with deposited collections (for limited and unlimited periods of time).
3. Archives of individual state administrative units (offices, institutions, industrial organizations), which gather materials produced by their mother institutions (including records destined for perpetual keeping);
4. Archives of political parties, trade unions, public organizations and associations, churches, and religious organizations. Archival materials are also to be found in numerous libraries (mainly research libraries) and museums run by the state and by local governments.

Three of the central archives are located in Warsaw:

1. Archiwum Główne Akt Dawnych (Central Archives of Historical Records; <http://www.agad.archiwa.gov.pl>).

The Central Archives of Historical Records were established during the Napoleonic period in 1808, as the General Archives of the Country. At present it stores the records of central and regional authorities produced prior to 1918, archives of the more important Polish families, and cartographic collections (seventeenth to twentieth centuries). As a result of the losses inflicted during World War II, this archive consists of only 7 km. of acts. It also includes a library consisting of over 22,000 volumes of books and periodicals, and about 600 titles of old prints.

2. Archiwum Akt Nowych (Central Archives of New Records; <http://www.aan.gov.pl>);

The Central Archive of New Records, was established in 1919 as a Military Archive. This archive has been known under its current name since 1930. It currently holds records of central government institutions, produced after 1918, and all national institutions and associations, as well as important individuals in political and public life.

3. Narodowe Archiwum Cyfrowe (National Digital Archives; <http://www.nac.gov.pl>).

On March 8, 2008, the Archives of Audio-Visual Records, founded 1955, have been transformed into the National Digital Archives (NDA). The aim of NDA is to provide digital files as a response to the development of recording, storing, and access technologies. NDA is obliged to

- Archive digital materials, including digital documents.
- Archive photographs, films, and sound recordings.
- Create digital files of hard copy materials.
- Share information about archives and make the collection accessible online.

In addition to the digital collection, the NDA also manages traditional archive materials. The NDA's collection contains almost 14 million photographs (including the oldest tintypes and daguerreotypes), 30,000 sound recordings, and 2500 films.

Until the late 1980s, Polish archives did not have any computers at their disposition. As time progressed this situation gradually started to change. The computerization of the state archives is supported by the Centralny Ośrodek Informacji Archiwalnej (Centre for Archival Information), a section of the Head Office of State Archives. In 2003 the Head Office of State Archives conceptualized the idea of an Integrated Digital System of the National Archival Holdings. The goals of the system were stated as follows: enhancement of the effective management of the national archival holdings; design of an effective and user-friendly system of archival information; facilitation of access to digital archives; attaining compatibility of the archives with the needs of online governmental administrations; and creation of an archival research network, which would integrate archival information holdings, with the holdings of library and research networks.

The archives have at their disposal a certain number of databases that enhance, to a certain extent, the exchange of archival information and provide better management of archival holdings. The databases in question are as follows: SEZAM (system of organising of archival holdings), PRADZIAD ("grandfather "birth, marriage, and death records register), SCRINIUM (register of documents dated prior to 1800), IZA (register of inventories of archival fond), KITA (technological computer information), ELA (people registering in archives), SUMA (system of archival material accessing), NADZÓR, RAP (register of archival research).

As of 2007, approximately half of the state archives had their own Web sites. The Central Archive of Historical Records is an exemplary case, with numerous inventories in the Encoded Archival Description (EAD) format accessible through the Internet or the Crown Metrica

search engine, which enables researching preparation act registers, of the Polish central government (<http://www.agad.archiwa.gov.pl/metodyka/metodyka.html>). This archive is currently developing an online order form for accessing archival records.

Computerization confronted the Polish archives with new challenges. Information systems require precision and therefore standardization becomes a necessity. Works on the Polish standard FOPAR were started in 1987. In practice, the archives did not choose the FOPAR standard, but adhered to the ISADAG (International Standard Description—General). Decision No. 4 of the General Director of the State Archives issued on February 1, 2005 concerning the structure and contents of the computer databases created and managed by the state archives, obliged the archives to use the ISADAG standard (http://archiwa.gov.pl/repository/decyzje/dec_4_2005.pdf).

The ISAD(G) standard has its Polish version. Six elements of the original have been considered as important for the international exchange of information and have been made compulsory: country code, archive, fond, shelf mark, title, date, level of description, size, and creator. The other elements of the description of the archival object are optional. The information on the object is inscribed into the EAD standard, which is managed by the American Library of Congress. ISAD (G) and EAD enable the description of archival objects at the level of the fond, series, subseries, inventory unit, and even individual document. Such a description can be supplemented by a digital object.

Politics of Representation in Museums

Louise Tythacott

Centre for Museology, University of Manchester, Manchester, U.K.

Abstract

This entry begins by examining key words, “politics,” “power,” and “representation,” as they relate to the museum. It then moves on to explore how the politics of representation have been manifested in displays. A range of exhibitions is examined, particularly in national, art, and ethnographic museums. The entry posits the case that museums are not simply neutral containers of objects, but are ideologically loaded spaces, and it demonstrates how museum displays have, over the past decades, become politically charged battlegrounds between differing communities.

INTRODUCTION

The political implications of representation in museums have come under mounting scrutiny over the past 20 or so years. The authority of the museum has been disputed, with the exhibitions becoming increasingly the subject of debate. This entry begins by reviewing theories of power and representation in the museum. It examines how these institutions have traditionally reflected the values of societal élites. It will be argued that museums are not neutral frames through which objects are viewed, but places where ideologies are manifested through the positioning and interpretation of objects on display.

The focus moves to the documentation of key exhibitions where the politics of display has come to the forefront of debate. Sections are organized around different museum types—national museums, art museums, science museums and finally, and perhaps most controversially, ethnographic museums.

MUSEUMS, POWER, POLITICS

Displays of power have always been what museums do.^[1]

If we consider the premise that, at its most general level, politics is associated with the workings of power,^[2] then museums have always been “political.” Since their inception these institutions have been embedded within, and represented, power structures in society. Many cabinets of curiosities of the sixteenth to seventeenth centuries (which were the precursors of the modern museum) began as elitist institutions designed to limit access to privileged classes.^[3] Such early collections often operated as status symbols for the aristocracy and royalty in Europe.^[4]

The modern museum emerged in the late eighteenth to early nineteenth centuries in an era of global politics and colonial domination, and when the vast collections of

Royal families in Europe were transferred to public ownership. The most renowned instance of the transformation of a formerly private collection to a politically charged symbol of a new regime is the Musée du Louvre, which opened in Paris in 1793. By the end of the nineteenth century, every Western nation had at least one major public museum. As collections shifted from private to public, so museums consolidated their social status, becoming bastions of European society. For authors such as Tony Bennett, “. . . their central message was to materialize the power of the ruling class. . . in the interest of promoting a general acceptance of ruling-class cultural authority.”^[5]

While museums historically formed part of systems of prestige, they continue to be associated with status and power today. Just as in the nineteenth century in Europe and North America when museums were established to consolidate wealth, so in places such as China, new building projects—in Beijing, Nanjing, and Shanghai—are being harnessed to assert China’s growing influence in the twenty-first century. There will be 1000 new museums built in China in the next decade and Shanghai alone is planning to open 150 by 2010.^[6] Macdonald characterizes such contemporary museums as “global symbols” through which “status” and “community” are expressed.^[7]

A number of influential authors have analyzed the operations of power in the museum. For example, Tony Bennett argues that in the nineteenth century museums became an important component of cultural governance, involved in processes of regulating the moral, mental, and behavioral characteristics of the population.^[8] Bennett notes that the spatial configuration of the nineteenth century museum—the balconies and courtyards, and display cases arranged along evolutionary ideas of progress—enabled them to function as a means for knowledge-control and the observation and control of behavior. Bennett characterizes museums as “agents for establishing and policing norms of public conduct.”^[9] By indoctrinating visitors with the current political ideology, they were able

to regulate the population: “Going to a museum, then as now is not merely a matter of looking and learning: it is also...an exercise in civics.”^[10] Bennett’s work draws on that of Michel Foucault in examining cultural technologies for exercising “disciplinary” or “governmental” power. According to a Foucaultian perspective, museums would be considered part of a system reinforcing the state’s hegemony.

Pierre Bourdieu too sees the art museum as closely tied to power structures.^[11] Working in the 1960s, he conceptualized the art museum as the exclusive domain of the cultivated classes, arguing that it was only those equipped by education who have a mastery of the codes and who are able to decipher the works on display. For Bourdieu, the art museum is a place through which the middle-classes and élites in society reinforce their sense of cultural distinction, perpetuating the notion of high art as exclusionary.^[12] Culture, power, and class are related here, legitimating social differences and reproducing relations of power. As an important cultural site for the definition of distinction and taste, museums in this view become instruments of class hegemony.^[13] Carol Duncan also conceptualizes the art museum as a “social, political and ideological instrument.”^[14] For her, like Bennett, they are “performative” environments. In particular, her writing focuses on their role as ceremonial sites that use display arrangements to promote national pride.^[15] The visitors to an art museum perform a “ritual,” which constructs them as ideal bourgeois citizens.^[16]

Museums, of course, may be read in ways other than as articulations of social and political power. Witcomb argues for a position in which museums are not always considered to be concerned with power relations and puts forward alternative readings of the museum.^[17] The notion of museum as an organ of the state may be clearly manifested in national museums but not particularly

evident in small, local sites—in community run or private museums. While acknowledging that many different types of museum exist, and that there is a range of funding regimes and sizes, here the focus is on exhibitions in larger museums, which are more clearly tied to systems of power and have been more consistently the subject of political debate.

Large civic or national museums have “status-conferring” roles: they are expected to present “authorized or established pictures of a nation’s history and culture.”^[18] Such museums are perceived to represent socially approved definitions of reality. As Riegel notes: “People look to museums as the arbiters of ‘high class’ taste, a source to be relied upon when it comes to matters of culture.”^[19] The social power of museums derives from this belief that their views are sanctioned by the state. Displays that represent a culture, a people, a religion, even a nation, as we see in a later section, assume considerable social authority.

One of the most obvious ways in which museums emanate power is through architecture and position. Often collections are housed in imposing buildings which have been likened to ceremonial monuments that emulate classical temples, medieval cathedrals, or Renaissance palaces.^[20] In the nineteenth century many were built in the style of Greek temples with columns, porticos, and steps (Fig. 1). Such architecture was intended to stand out in the cityscape, marking these as sites of cultural significance. Riegel notes how the Royal Ontario Museum (ROM) in Canada, “exudes authority: the architecture is monumental, the technical aspects of exhibits are superbly executed.”^[19] This observation applies equally to such edifices as the British Museum, the Louvre, the Metropolitan Museum, New York, and indeed many of the large national institutions, or what have been termed “universal museums.”

Fig. 1 National Archaeological Museum, Athens.
Source: Photograph taken by the author, 2008.

The location of museums is also important. In the nineteenth century, many were built in the centre of towns or cities, near other places of civic authority, such as the town hall and library. Giebelhausen refers to this as the “symbolic geography of power.”^[21] The siting of major museums in visually prominent positions continues today—one thinks immediately of Bilbao’s Guggenheim, Te Papa Tongarewa in New Zealand, the National Museum of Australia, or London’s Tate Modern.

It is not only external architecture but the inner codes and conventions that are indicative of the authority that museums wield. Bennett refers to these as the “regulation of conduct”^[22]—the silence imposed, the hushed conversations, the prohibition of daily activity, the slow and careful movements, the sense of reverence. Behavior inside is marked by a particular type of receptivity and contemplation that Carol Duncan likens to a ritual^[23]—and most of us conform to this. As well as the modification of behavior, the messages imparted through display exert powerful effects. Exhibitions are generally not authored or dated, and seem intended to be read as the anonymous “voice” of the institution. The workings of the museum—the decisions made about how to display objects, who decides on themes, and why—are usually left opaque. Lavine and Karp argue that it is precisely the “neutrality” of museums that enables them to become instruments of power.^[24] People think that what they are looking at in a large public museum is the undisputed “truth.”

REPRESENTATION IN THE MUSEUM

Let us now examine the relationship between museums and representation. Stuart Hall defines representation as the “production of meaning through language,”^[25] and museum displays, he argues, can be seen as “systems” or “practices of representation,” in which objects stand for verbal concepts.^[26] Rather than “words or images,” then, the elements of this system of signification are things—their arrangement and display within a physical space.^[26]

It is through objects and exhibitions that museums construct their most powerful representations. Hooper-Greenhill argues that displays are “visual public statements” of an institution.^[27] The selection of certain objects and the exclusion of others, their arrangement on display, the type of language chosen for text panels, the use of photographs, lighting, display devices (cases, plinths, etc.) and interactives all function to construct certain images: “Every choice—to show this rather than that, to show this in relation to that, to say this about that—is a choice about how to represent.”^[26] For Hall, museum representations can never be objective, neutral, or value-free: they will always articulate particular perspectives. Bennett,^[23] Duncan,^[23] and others argue also that the museum is a place that manifests dominant ideologies: they do not passively display objects but actively construct

the spaces in which things can be viewed. Being able to order the representation of the world carries with it a certain authority—“the power to name, define, classify and re-present.”^[28]

Hall maintains that politics has to do with the *effects* and *consequences* of representation.^[29] It is the way the objects, the texts, and the spaces are read by visitors that enables them to become political. For some, the entire structure of display is permeated with power relations. Riegel argues that the practices of representing culture through imagery is:

...an inherently political act which separates those who view the exhibit from those who are on display. The act of viewing is related to the acts of ordering, defining and representing according to categories of the ‘viewing’ culture.^[30]

Lavine and Karp too believe that the very nature of exhibiting makes it a contested terrain: “Decisions are made to emphasize one element and downplay others, to assert some truths and to ignore others.”^[31] While museums promote particular perspectives, they also, inevitably, conceal others. Museums have the power to include and exclude, to interpret objects, peoples, and cultures in specific ways. In the nineteenth century, many ethnographic museums, for example, placed the material culture of non-Western peoples in evolutionary sequences in order to promote the idea of a hierarchy of progress from “primitive” to “civilized.” Such a system of representation, now politically unacceptable, was a product of the ideology of the time.

Over the past 20 or so years, the museological literature has been increasingly concerned with the processes of representation and its political effects.^[32–39] Since the 1980s, in particular, the authority of the museum has been challenged and groups have questioned the right of institutions to control how their cultures are displayed.^[31] Communities and individuals have raised questions relating to power, authority, and representation. Who decides on what should be selected for exhibition and why? Who authors displays? Who should represent and speak about cultures? Whose voices are heard? Whose voices are excluded? What are the languages of representation? Who is empowered and who is disempowered by particular methods of display?^[40] (Fig. 2).

The above discussion has outlined a framework for considering the museum as a site of power and a place of representation. Next let us examine some examples.

NATIONAL MUSEUMS: POWER, IDENTITY, AND THE NATION

More than any other, a national museum may be considered part of a state’s political apparatus of representation.

Fig. 2 Mahayana Buddhism case, World Cultures gallery.

Source: Photograph taken by National Museums Liverpool, 2008.

Large “nationals” play important roles in expressing established values and sanctioning the images a nation wishes to convey of itself. Some national museums are utilized overtly for political purposes, as tools of the state or instruments of propaganda. For example, the Museum of the Chinese Revolution, which opened in Tiananmen Square in Beijing in 1960, is a political institution, serving the interests of the Chinese Communist Party.

But what exactly is meant by the idea of the nation and how can this be manifested in a museum? Benedict Anderson famously argued that the concept of “nation” is imagined because “members of even the smallest nation will never know most of their fellow-members, meet them, or even hear of them. . . .”^[41] The “nation,” for him, is created by people to serve specific purposes. It is abstract and anonymous and needs symbols as a way to manifest itself—flags, coins, monuments, uniforms, and, of course, museums, give the idea of the nation a physical presence. In this sense, national museums function to create bonds between individuals and the abstract political concept of the state. Exhibitions—or representations—within these buildings assume a particular social significance.

We saw earlier how there was a trend in the eighteenth and nineteenth centuries for the private collections of the aristocracy and royalty in Europe to be transformed into national museums. This was also a key period in the formation of modern nation-states in Europe, and museums were often established, then harnessed, as manifestations of national pride.^[42,43] In other parts of the world, national museums have been created in response to radical political change or independence. Throughout the nineteenth and twentieth centuries a host of countries, in throwing off the yoke of colonial rule, used museums as a way to articulate a new sense of national identity. Greece is a good example. The year the Greek state was legally established, in 1834, the first National Archaeological Museum was constructed in Athens.^[44] The new Greek nation was characterized by its fascination with the classical past, and

museums in particular were mobilized as political symbols of a new independent identity. In Mexico too, museums and archaeological objects became entangled in the processes of nation-building after the Revolution. Four years after independence from Spain, in 1825, a decree was issued for the establishment of a National Museum (though it would not be until 40 years later that the museum was built, in the city centre, near the presidential palace).^[45] By the early twentieth century, the state had begun to take more direct control of the representation of the country, as the president, Porfirio Díaz (r. 1876–1880 and 1884–1911) patrolled the national museum, approving or disapproving the content of exhibition halls.^[46]

This pattern between political independence and the establishment of national museums continued into the twentieth century. The National Museum of India in Delhi, for example, was created the same year as independence in 1947. The National Museum of Pakistan in Karachi was set up shortly after, in 1950. The first National Museum of Nigeria was opened in 1952. (Nigeria became independent in 1960). Though these links must not be overstated—for countries gain independence and do not construct national museums—these institutions nevertheless are clearly considered a means to articulate new nationhood. Patrick Boylan has even suggested that building a national museum is one of the top four priorities for newly independent governments. The four are: 1) a national defence force; 2) a national broad casting service; 3) a national museum; 4) a national university.^[47]

The National Museum of Scotland is worthy of consideration here—this too is an institution that emerged at a key moment in Scottish political history. It opened in Edinburgh in 1998, seven months before the British Queen opened the first session of the Scottish Parliament in July 1999. Donald Dewar, the First Minister of Scotland, in fact drew a parallel between the museum and the new Scottish Parliament, describing both as “symbols for a cultural renaissance in Scotland.”^[48] As the plans

progressed all “non-Scottish” elements were deleted. The museum became more rigorously thematic, documenting the story of the nation. It starts with *Beginnings*, (geological foundations and early wildlife), moving on to *Early Peoples*; *The Kingdom of the Scots*; *Scotland Transformed* (eighteenth century); *Industry and Empire* (nineteenth century); *Victorian and Edwardian Life* and, finally, *The Twentieth Century*. The choices and the arrangement of the galleries and their associated interpretation are deliberately configured to promote narratives of Scottishness (Fig. 3).

Since the mid-1980s, a number of new national museums have emerged offering different political representations of a country’s history, culture, and identity. What seems to distinguish the national museums of the late twentieth to early twenty-first centuries is that they consciously celebrate diversity and equality. The idea of the nation tends to be defined as a blend of voices and groups marginalized through dominant white narratives of history are prominently addressed. Former colonial powers, in particular, have come under pressure to reappraise their representations of the past, especially those related to imperialism. The National Museum of Australia, in Canberra, which opened in 2001, is a good example, a place that consciously celebrates the Aboriginal peoples and their contribution to, and place within, the nation. This is also evident at the National Museum of New Zealand—Te Papa Tongarewa—which opened in 1998. Te Papa is a “bicultural” institution, with a Maori name, and it celebrates the Maori presence in New Zealand as never before. The museum calls itself a “gateway, or an encounter with the essence of New Zealand’s land and people,” its key task being to preserve and present the *taonga* (treasures) of New Zealand’s indigenous people.^[49]

Such national museums operate on a political level, as symbols of newly configured nationhood. It is evident that objects and collections here may be manipulated for ideological purposes. We now turn to examine how politics has been reflected in other museum types—firstly those devoted to art.

INSTITUTIONAL CRITIQUE AND “SENSATION”: THE POLITICS OF REPRESENTATION IN ART MUSEUMS

It is in the art museum, with its predominant focus on the singularity of the object, that the codes of behavior seem most pronounced, the rituals of visiting heightened and the reverence of things most evident.^[23] When this hallowed world and contemporary issues clash, the politics of representation is intense.

From the 1960s, artists started to explicitly engage with the idea that the gallery environment is socially, politically, and institutionally conditioned. Marcel Broodthaers, Daniel Buren, and Hans Haacke were associated with what came to be known as “Institutional Critique,” a fundamental questioning of the practices of the art museum. In their various ways, they drew attention to the power of the museum apparatus in promoting taste and value, and used visual means to expose the ideological underpinnings of this institution.^[50] More recently, in the 1990s, Fred Wilson’s work has exposed the racial and political implications of display in installations such as “Mining the Museum” at the Maryland Historical Society.^[51]

Hans Haacke’s documentation of high art’s corporate affiliations is perhaps the most overtly political. In 1970 he created an installation at the Museum of Modern Art (MoMA) in New York which asked “Would the fact that

Fig. 3 Display at the National Museum of Scotland. Source: Photograph taken by Kostas Arvanitis, 2008.

Governor Rockefeller has not denounced President Nixon's Indochina Policy be a reason for you not voting for him in November?" with two ballot boxes: there were twice as many "Yes" as "No" ballots. The installation also criticized a board trustee, and MoMA itself. The following year, Haacke planned a show at the Guggenheim Museum to expose the questionable transactions of a real-estate businessman, Harry Shapolsky, and his links with the museum's trustees, but this was cancelled by the Director. In another exhibition at the Museum of Modern Art in Oxford in 1978, Haacke's "A Breed Apart" criticized British Leyland for exporting vehicles for military use in apartheid South Africa.

Not only have artists deliberately drawn attention to political injustices—Mark Wallinger's installation "State Britain" at Tate Britain in early 2007 is a good example, a 40 m long replica of the minipeace camp run by Brian Haw opposite the Houses of Parliament—but art exhibitions themselves have become (sometimes unwittingly) entangled in wider political debates. "Sensation: Young British artists from the Saatchi Collection" is a notable case. In 1997 the display created a stir at the Royal Academy, London, because it included the painting, "Myra," an image of the child murderer, Myra Hindley, by Marcus Harvey, made up of hundreds of copies of a child's handprint. Winnie Johnson, the mother of one of Hindley's victims, asked for the portrait to be excluded. Along with supporters she picketed the show during its first day. Despite the protests, the painting remained on exhibition. Windows at the Royal Academy were smashed and demonstrators threw ink and eggs at the picture. It was taken off display for conservation and upon return, was placed behind glass and guarded by security officers.

"Sensation" traveled to the Brooklyn Museum of Art in New York City (October 2, 1999 to January 9, 2000) and here too it was met with political protest, this time focusing on a different image and issue. A public battle erupted around a painting, "The Holy Virgin Mary," by Chris Ofili. The press incited controversy by reporting that the work had been smeared with elephant dung. New York Mayor, Rudolph Giuliani, declared the show to be "insulting to Catholics." Protesters outside the museum handed out vomit bags and threw manure in protest. As a precautionary measure, the museum placed "The Holy Virgin Mary" behind protective glass. Even so, on December 16, 1999, a 72-year-old man was arrested for "criminal mischief" after smearing it with white paint. The Catholic League for Religious and Civil Rights issued press statements asking for a boycott of the museum and asking citizens to write to New York City Council demanding that the museum have its grant withdrawn. Two days before the opening, New York City Hall indeed severed its funding and threatened to evict the exhibition from the building. A court ruled against this on the grounds of freedom of expression.

"ENOLA GAY": HISTORY, WAR, AND POLITICS

Science museums too have become sites for the struggle over representation—the most renowned example being the display of "Enola Gay" at the Smithsonian's National Air and Space Museum (NASM) in Washington, D.C. in 1995, which aroused levels of controversy comparable to "Sensation."

The fuselage of "Enola Gay," the B-29 bomber that dropped the atomic bomb on Hiroshima, went on exhibition to commemorate the end of World War II, and the aeroplane's role in securing Japanese surrender. An earlier planned exhibition "The Crossroads: the End of World War II, the Atomic Bomb and the Origins of the Cold War" had been cancelled and after much discussion, the fuselage alone was allowed a public airing.^[52] Yet this created huge controversy, particularly amongst veterans and the Air Force Association (AFA), who attacked the Smithsonian's interpretation for being "pro-Japanese" and "anti-American."

Dubin notes how the display was significant in coinciding with a period when Japan was a major U.S. trading partner, and sensitivities had to be handled carefully.^[53] The exhibition texts were monitored and went through many amendments—some of which were requested by the AFA.^[54] Both veterans and the AFA in fact accused the curators of only wanting to show the devastation the bomb had caused, and exaggerating Japanese suffering. They complained that the Japanese were being turned into tragic victims, or, worse still, heroes, and that the Allies by contrast were demonized as ruthlessly aggressive. The loan of material from Hiroshima and Nagasaki and planned videotape testimonies about the bomb's legacy came under particular attack.^[55] It would not be possible, they argued, to display a balanced perspective if only the "last act" was shown.^[56] The curators were accused of political bias. The House Speaker, Newt Gingrich argued: "Political correctness may be okay in some faculty lounge, but...the Smithsonian is a treasure house that belongs to the American people, and it should not become a plaything for left-wing ideologies."^[57] Veterans wanted to counteract curatorial "bias" by including information on the Japanese war camps, the numbers of Allies lost in the Pacific, images of disabled veterans, and the numbers of lives saved because the bomb brought the war to an end.^[58] Fundamentally, of course, their concern was to legitimize the bombing and pay tribute to the bravery of their comrades. Eight conservative members of the House of Representatives were outraged by the low figures suggested by curators for American casualties had the bomb not been dropped, and called for the Director, Martin Harwitz to resign. Harwitz indeed left in the wake of controversy.^[59–61]

Peace campaigners were also enraged. On the opening day, 21 people were arrested during a demonstration, some bearing signs urging "Never Again" or "No More

Hiroshimas.” Four days later, the museum closed for 90 min after three protestors poured human blood and two bags of ashes on the fuselage. The protestors were charged with, and found guilty of, felony destruction of government property.^[62]

During the development of the exhibition, some had wanted the plane to be displayed without comment, so that it “could speak for itself”^[63]. “Critics came to prefer a display of the aircraft in minimalist interpretative dress—precisely because they did not want to impose any particular reading on museum visitors.”^[64] One pilot, for example, said it should be displayed alone.^[64] Yet, as we saw earlier, objects can never be interpreted neutrally. The apparatus of the museum will always influence the angle from which an exhibition is understood. The choice of words on texts and the other associated documentation—the information that is included *and* excluded—work to produce certain readings.

This particular exhibition demonstrates the difficulty of representing opposing points of view in the public space of the museum, particularly in such a culturally authoritative institution as the Smithsonian.^[65] These controversies revolved around the perspective from which the war should be recounted. Critics were concerned about the authorship of the texts and whether they were biased. They wanted to know who was being celebrated—the Americans or the Japanese? Who was being blamed? Whose voices were being heard?

It is significant that the display was mounted at the Smithsonian, one of America’s most powerful national museums. As an American Legion Spokesman noted, “this is. . . a public institution, where the impression is that anything it says is official history.”^[66] The authority of this museum functioned to underline the idea that the “truth” was being presented—and this is the reason why exact interpretations were so carefully monitored. In the next section we examine other groups whose historic injustices have created impassioned debate within a very different type of museum, and we see how controversial racial imagery was taken to be the officially sanctioned view due largely to its display in one of North America’s most authoritative institutions.

REPRESENTING “OTHER” CULTURES: POLITICS IN THE ETHNOGRAPHIC MUSEUM

While museums in general have come under increasing attack in recent decades, it is in the sphere of ethnographic exhibitions that the political dimensions of display have come under the sharpest scrutiny. Ethnographic museums, above all others, have become targets of controversy. Hooper-Greenhill writes that, “the negotiation and contestation of museum authority has been at its most evident in relation to colonial collections”^[67] (Fig. 4).

Why should this be? In many ways it is due to the historical formation of collections. Many ethnographic collections were created in the nineteenth to early twentieth centuries as a direct result of colonialism—and under such regimes, it is well documented that a great number of objects and collections were taken by force. The display strategies of ethnographic museums in the nineteenth century were also clearly linked to colonial ideology. Early ethnological galleries promoted dominant beliefs in the superiority of Western cultures. In particular, evolutionary displays visualized unequal power relations between peoples and implied the need for progress from “primitive” to “civilized.” By the end of the nineteenth century, evolutionism had come to dominate the arrangement of non-Western objects in ethnographic museums.^[68]

While evolutionary displays were largely abandoned in the twentieth century, ethnographic museums continued to be the keepers of other people’s material and the interpreters of their histories. Museums continued to assume the undisputed power to speak for and represent other people. Here indigenous groups never had a voice: they were discussed, exhibited, and interpreted, but were never able to “talk back.” As a result, for some, they became symbols of white power and domination, perceived “. . . to serve a cultural élite, staffed primarily by whites, reflecting white values, and excluding from the interpretative process the very peoples whose cultures were represented in the collections.”^[69]

In the 1980s, alongside wider social and political changes, indigenous peoples started to challenge the authority of museums to represent their cultures. Communities began to demand a greater voice in how they were being displayed. A series of exhibitions at this time resulted in the politics of representation being foregrounded as never before—such exhibitions became implicated in politics because of tensions between who was doing the exhibiting and who was being exhibited.^[70]

This section documents three exhibitions in the 1980s that illustrate well the climate of the times.

The earliest was “Te Maori” (literally “the Maori”) which toured the United States between 1984 and 1986, before returning to New Zealand in 1986 and 1987.^[71] This is considered a turning point in museum presentations of Maori culture and more widely in the relationship between Maori and museums.^[72,73] For the first time, Maori people were consulted about their tribal *taonga* or treasures.^[74] Not only did the exhibition combine Maori objects from museum collections all over the world, it also created links between collections and contemporary Maori people. It also brought to the surface issues over who should control the representation of their heritage. Elders and scholars, who were actively involved in setting up the exhibition, made recommendations to museum professionals in the light of the show—one of which was that the Maori should determine how their *taonga* is to be interpreted.^[75] As a result of the exhibition, a conference was held in 1990 in

Fig. 4 Entrance to the World Cultures Gallery, World Museum Liverpool.

Source: Photograph taken by the author, 2005.

Wellington, where plans were launched for the creation of a museum of New Zealand, Te Papa Tongarewa, which, as we saw in an earlier section, opened in 1998.

Another exhibition in which politics came to the fore was the “Spirit Sings: Artistic Traditions of Canada’s First Peoples” at the Glenbow Museum, Calgary, Canada in 1988. This was organized in association with the Calgary Winter Olympics and was designed to highlight the rich artistic and cultural traditions of Canada’s native peoples. However, the exhibition became caught in the cross fire of a political campaign to support land claims by the Lubicon Lake Cree of northern Alberta. The Lubicon were demanding a boycott of the Winter Olympics in order to draw attention to their 50-year dispute with the Canadian government. At the same time they called for a boycott of the exhibition. The group was particularly incensed by the sponsorship of Shell Canada Ltd., who were actively involved in harmful drilling activities on land the Lubicon claimed as their own.^[76] The exhibition created a great deal of publicity and, perhaps for the first time, made people realize that museums cannot simply ignore contemporary issues such as land claims when presenting an exhibition of the cultures of indigenous peoples. As a direct result of the show a First Peoples–Canadian Museums Association Task Force was established jointly sponsored by the Assembly of First Nations (the preferred term for indigenous peoples in Canada) and the Canadian Museums Association.^[77] After several meetings, it produced recommendations on how to improve relations between First Nations and museums. Since this date there has been a dramatic change in power relationships—a shift from Canadian museums telling First Nations about their cultures, to dialogue, and inclusion.

A year later, in Canada, an exhibition at the ROM turned out to be the most politically controversial in its history (November 1989–August 1990). It was curated by a cultural

anthropologist, Jeanne Cannizzo, who set out to show the origins of the ROM’s African collection within the context of Canadian imperialist history. However local Afro-Caribbean communities were highly offended by it, labeling it racist. They formed an ad hoc group, the Coalition for Truth about Africa, and held protests every Saturday afternoon outside the museum. They also petitioned the ROM for the exhibition text to be changed or the exhibition to be closed, but the museum did neither. The main problem was that the displays represented the voices of “white” people—Canadian soldiers and missionaries—without incorporating African voices. There was ambiguity in messages in texts and the catalog, and an impression that the exhibition was celebrating rather than critiquing the role of missionaries and colonists in Africa.^[78] The use of irony in text panels, in particular, was misunderstood. Although Cannizzo italicized terms such as “barbarous” and “savage customs” with the intent of questioning them, the placement of such problematic language in italics next to visual images was not taken as a critique, but rather as an affirmation of this problematic imagery.^[79] This museum—one of Canada’s most prestigious and powerful—was simply thought to be condoning contentious colonial and racist perspectives.^[80]

The lack of consultation with African communities at a time when they were demanding a voice only inflamed anger.^[81] Communities contested the ROM’s right to ownership of its African collection, as well as the museum’s ability to present an exhibition of Africa. They questioned the authority and ability of Cannizzo—a white cultural anthropologist—to “represent” Africa.

MUSEUMS AS “CONTACT ZONES”

As a result of these exhibitions and the wider critiques that emerged in the 1980s, museums became, in James

Clifford's words, "contact zones."^[82] The historic aloofness and neutrality of the museum seemed to have been broken open by communities who had previously been ignored. Questions of power and authority came to the fore, as did questions about who has the right to speak for and represent whom. Ethnographic museums started to realize that they had to redefine their practices and strategies of display. In becoming sensitized to the political implications of their role, some began to acknowledge the unequal power relations that their collections and historic representations had been predicated upon.

The changes taking place within ethnographic museums have had a significant impact on the work of curators. Over the past decade or more, a new type of museum professional has emerged, who see themselves as "facilitators" or "stewards" of collections on behalf of communities. New forms of curatorship are increasingly sensitive to multiple voices and diverse audiences (Fig. 5). In ethnographic museums today, it is often the case that curators are not the sole voices of authority in interpreting and displaying objects, but acknowledge an obligation to involve source communities in the care and representation of collections.^[83] Emphasis is placed on the active involvement of indigenous curators, consultants, or advisors, especially in North America, New Zealand, and Australia.

One of the most significant developments here is the National Museum of the American Indian in Washington, D.C. Opening in 2004, it represents an unprecedented collaboration between the Smithsonian and Native Americans. The museum was authorized by Congress in 1989, and from its inception was a political creation. It has three facilities: The George Heye Center, Manhattan opened in 1994; the Museum building itself in Washington, D.C. and a Cultural Resources Centre in Maryland.^[85] Native peoples had the authoritative role in approving the architecture, design, and displays. The interpretation and

presentation of the collection was planned in consultation with tribal groups, and special regard was given to the exhibition of sacred or sensitive material. Material culture and sacred traditions are presented by native people in ways that reflect *their* values and viewpoints.^[84]

What we are seeing in the twenty-first century is a transformation in the power relations in ethnographic museums. Clifford describes this as "... a shift from a 'colonial' to a 'cooperative' museology."^[85] Museums and indigenous peoples have started to work together to redress the imbalances of cultural representation, using collections for promoting cross-cultural awareness. Yet such changes have been uneven, with museums in the United States, Canada, Australia, and New Zealand being much more active than those in Europe. In certain places, however, museums have indeed become institutions through which indigenous peoples now finally have a "voice."^[86]

CONCLUSION

In this entry we have seen how museums have been intimately related to power and politics, traditionally reflecting the interests of those dominant in society. We have looked at how the authority of the museum emanates from a range of structures—architecture, location, the historical formation and ownership of collections, the themes and arrangements of exhibitions, the selection of objects, the authorship of displays, and the inclusions and exclusions in textual interpretation. We have also seen how the power of the museum is evident in its operation as a social space that modifies public behavior and how museums "represent" through the display of objects.

The museum as an institution has come increasingly under attack in the past 20 or more years, with previously marginalized groups questioning its traditional authority.

Increasingly exhibitions have become the subjects of criticism and, at times, impassioned debate. Some shows, as we have seen, have unleashed dramatically opposing views. Controversy can erupt over the display of an aeroplane, a painting or the representation of “Africa”—particularly when touching upon topics such as war, religion, and race. In the ethnographic museum—and in other places too—the power issues often lie in the discrepancy between those who control access to, and those who want to have access to, collections. As exhibitions become more concerned to address contemporary concerns, it seems inevitable that they will become more controversial.^[87] Increasingly, in the twenty-first century, museums are politically charged spaces, not neutral sites of display.

Popular Literature Genres

Barry Trott

Williamsburg Regional Library, Williamsburg, Virginia, U.S.A.

Abstract

This entry defines the concept of “genre” in relation to popular reading. It then briefly reviews the eight traditional genre categories, discussing their forms, structures, history, major subgenres, and trends. The increasing interest in narrative nonfiction and its relation to genre is explored. Three emerging genres are then discussed as examples of new developments in the field. The topic of reading interests versus genre is examined, and cross-genre writing and genre separation are discussed.

INTRODUCTION

The idea of genre provides readers and librarians a convenient mechanism for categorizing and providing access to fiction writing. As Ursula K. Le Guin notes, “The concept of genre is a valid one. We need a method for sorting out and defining varieties of narrative fiction, and genre gives us a tool to begin the job.”^[1] Understanding genre fiction allows librarians to analyze

the stylistic elements that authors use that will appeal to readers—of fantasy, Westerns, romances, mysteries, etc. The concept of genre is useful here because it defines a set of precepts that describe a certain style of writing. This knowledge allows librarians to connect readers to books that they will enjoy. In fact, it is an understanding of what the appeals of a particular genre are that will allow librarians to make connections between books and authors that may be separated by genre classification.^[2]

A readers’ advisor who grasps the broad concepts of genre appeal will be able to make reading suggestions both within genres and across genres, expanding the range of possible titles to offer readers. Here, genre becomes a useful tool for offering suggestions to readers. It is a concept that most readers understand. Librarians frequently hear from their users, “I like mysteries,” “I love to read Regency romances.” As an increasing number of authors (Michael Chabon, Audrey Niffenegger, Mary Doria Russell, and Cormac McCarthy to name only a few) write novels that blend genres, an understanding of the appeals of the various genres becomes even more essential to the provision of readers’ advisory services to the reading public.

In the library world, genre has also been an important mechanism in collection arrangement. As in bookstores, many libraries separate some parts of the fiction collection by genre. Most commonly, libraries offer sections of mysteries, romances, science fiction, and so on. Breaking out large fiction collections into smaller, more browsable units may offer readers an easier time in locating desired

materials. Sharon Baker’s book *The Responsive Public Library: How to Develop and Market a Winning Collection* does a good job of summarizing the research done on genre separation and shelving.^[3] Baker notes that in addition to increasing reader satisfaction, separating genre fiction collections generally results in higher circulation of library materials.

As in all areas of fiction, genre writing generally has a set of characteristics that can be defined and described. These patterns offer a sense of familiarity to the reader, and make a substantial contribution to the continuing popularity of genre fiction among readers. Like the structures of formal poetry, the structures of genre fiction create a frame within which authors can develop stories that will appeal to a wide range of readers. Crime fiction, most commonly centers around the concept of bringing order and justice to a chaotic world. Within that frame, mysteries stories can vary from the cozy to the graphic, and from the lyrical to the terse. Similarly, fantasy and science fiction writing allows the reader to ponder on the structure of the world. In these speculative genres, the author asks the reader to consider the question of whether society has to be as it is now.

In their landmark work on readers’ advisory services, Joyce Saricks and Nancy Brown developed the concept of using appeal characteristics to more logically connect readers to the stories that they are seeking.^[4] When looking at genre fiction, two of Saricks and Brown’s appeal factors are of particular importance to readers of genre fiction. The appeal of character is clearly a major draw for readers of genre fiction. Readers come to identify with the character, whether that is the detective in a mystery, the sword-wielding hero of a quest fantasy, or the love-struck protagonist of a romance. Furthermore, the importance of character to genre readers is seen in the affection that many readers of genre fiction have for series characters. The pleasure of following a particular character from book to book is clearly one that genre readers enjoy. The second important appeal factor to consider in

looking at genre fiction is the setting, both geographic and chronological. Many readers of genre fiction look to be transported to other places and times. This factor can be a manifestation of an interest in learning something new about a historical period or a particular place, or simply a desire to travel vicariously to a different locale that the reader enjoys. The other appeals discussed by Saricks and Brown also all apply to the enjoyment of genre fiction. Mood, tone, language, and story are as important to genre readers as they are to readers of other fiction.

Most discussions of popular genre fiction separate the field into eight areas: Adventure, Crime Fiction, Fantasy, Historical Fiction, Horror, Romance, Science Fiction, and Westerns. The next section will examine each of these traditional genres, looking at their basic structures, their foundations, their major subgenres, and their primary appeals to readers.

ADVENTURE

Novels that fall in the adventure genre are invariably fast-paced, plot-driven stories. These are stories that appeal to readers who enjoy breath-taking escapes, hair-raising exploits, and resourceful heroes. Though enjoyed by both male and female readers, the protagonists of adventures tend to be male, usually blending the intelligence of a Sherlock Holmes with the athleticism of an Olympic star. Readers come to these stories looking for action and suspense. At their most elemental, adventure stories present a main character, frequently on his own, with little assistance, who finds himself in danger and spends the rest of the story extricating himself from the problem. In the course of finding safety, the hero generally also saves some portion of society from the machinations of the evil-doers. Often these heroes exhibit powers of physical strength, intellectual acumen, and recuperation that are beyond the norm. Readers surrender disbelief here in order to enjoy the thrilling narrative. In many stories in the adventure genre, a secondary appeal is in the intricate details the author uses to construct the story. The minutiae of weaponry and equipment are frequently important to readers, and they look for authenticity as well as for action. In other adventure novels the particulars of legal or medical proceedings draw the reader into the tale. Adventure novels can be grouped into several subgenres, each of which has its readers. Military adventures can be either contemporary (Tom Clancy) or historic (Patrick O'Brian). The espionage subgenre has survived the end of the Cold War, and flourishes again with the rise of global terrorism. Legal and medical thrillers, such as those written by John Grisham or Robin Cook examine corrupt practices and frightening pandemics. Inspirational thrillers blend Christian themes with action-packed adventure (see Frank Peretti or Tim Lahaye). In all cases though readers are looking for an adrenaline jolt that will keep them glued to the pages.

CRIME FICTION

Crime fiction is one of the most pattern driven of the genres. Readers are drawn to these stories for the sense of resolution that they bring. The seeking out of justice is at the heart of the crime novel. The typical storyline features the commission of a crime (usually, but not exclusively, a murder), the arrival of the detective (amateur or professional), the investigation of the suspects, the solution of the crime, and the bringing of the criminal to justice. As in all genre fiction though, the way the author chooses to follow this pattern varies widely. The subgenres of crime writing are numerous, though they all reflect the basic structure outlined above. The early days of crime fiction (in the early twentieth century) were predominated by the puzzle mystery (Agatha Christie's Hercule Poirot and Miss Marple mysteries being typical examples), where the author sprinkled clues to the crime throughout the story, and the reader could solve the crime along with the detective. These cozy mysteries often featured an English setting and an amateur detective. Following the First World War, a new, harder-edged mystery story came to prominence, and readers began to enjoy the exploits of the hard-boiled detective, who solved crimes with his fists as much as his intellect. Here, the puzzle was less important and the reader began to follow the exploits of the detective rather than solving the crime in tandem with the detective. Writers such as Raymond Chandler and Dashiell Hammett led the way here. In the last quarter of the twentieth century, crime writing expanded its scope even further. Women and minorities started appearing as detectives, and a host of subgenres grew in popularity, including the heist caper (usually told through the eyes of the criminal, see Donald Westlake's *Dortmunder* series), historical mysteries (taking detection as far back as the days of the pharaohs, Ellis Peters's *Brother Cadfael* books did much to promote this subgenre), forensic thrillers (featuring the often grisly details of pathologists as central to the story, Patricia Cornwell and Kathy Reichs both are key authors here), police procedurals (for readers who enjoyed the details of policing, P.D. James, in England, and Ed McBain, in the United States provide benchmarks for police crime fiction), paranormal mysteries (blending elements of fantasy and science fiction with crime stories, see Kim Harrison, Jim Butcher, or Eric Garcia), and the new cozies (with a range of amateur detectives solving crimes while running B&Bs, herb shops, quilt stores, etc. among the leading authors here are Susan Wittig Albert, Earlene Fowler, and Carolyn Hart). As the twentieth century ended, there were several new developing trends in crime writing in addition to the expansion of the subgenres. Authors began to take a much more realistic approach to crime, resulting in darker, more violent, stories (George Pelecanos, Dennis Lehane, and Ken Bruen among others). Societal concerns began to be reflected in the crime fiction of such writers as Sara Paretsky and Marcia Muller. The

rise of the serial killer novel paralleled the reporting of this sort of crime in the media. In the early twenty-first century, terrorism at home and abroad has become a central theme in much crime fiction. In addition to darker themes, crime fiction also has seen an increasing interest in the lives of the detectives. Crime writing now is often as much about the development of a series character as about the solution of the crime. The lives of the detectives are of great interest to readers, and family relationships and other personal details are sought out. Investigators are frequently dealing with problems in their own lives as well as with the misdeeds of others. Along with this trend toward darker detectives, contemporary crime novels frequently have a more ambiguous sense of justice. The criminal may never be brought to trial or serve time. Sometimes it is a corrupt state that allows criminals to get off, but it is not uncommon for extra-judicial justice to be meted out by the detective or by the victim's family or friends. It is this sense of order restored that is at the heart of the crime novel.

FANTASY

The story of a struggle between good and evil unites much of the writing in the fantasy genre. From the earliest times, people have told tales of the conflict between the dark and the light in order to reassure themselves that there is some chance to bring order out of the chaotic world. Fantasy novels continue to offer this hope to readers. In most fantasy fiction new worlds are created, or the existing world is reshaped, in order to provide the backdrop for the story. Fantasy invites its readers to suspend their understanding of the natural world and enter into a new place where the unexpected becomes real, and where magic replaces science as a source of power. The level of magic in the story may be quite variable. Earlier fantasy stories were often centered around the use and misuse of magic (Tolkein's Ring series for instance). In later fantasy fiction, magic often has a more ambiguous and less central role, with the exercise of power taking a toll on those who choose to use it. Although myths and tales of magic have been in circulation as long as people have been telling stories, beginning in the late nineteenth century a style of writing, typified in the works of George MacDonald and Lord Dunsany, emerges that would be recognizable to today's fantasy reader. The popularity of these early titles encouraged the growth of the genre, and by the end of the twentieth century, fantasy writing was flourishing among readers. In the early twenty-first century, much fantasy writing is looking at darker themes, and it is frequently more challenging to distinguish between good and evil than it was in the early days of fantasy writing. Much of the appeal of the fantasy genre comes from the intricate worlds created by the authors. Writers such as Robert Jordan and Lois McMaster Bujold create sprawling,

multi-title series featuring recurring characters who move from novel to novel. Readers come back again and again to these stories to discover what is going to happen to the characters. Character is complex in fantasy, with a multiplicity of fantastic creatures in addition to the human characters. Fantasy is also frequently concerned with things—rings, swords, helmets, jewels, etc. These sorts of potent icons give power to those who wield them, and feature prominently in much of fantasy writing. Fantasy fiction has a variety of subgenres of interest to readers. Much early fantasy was of the “swords and sorcery” variety, featuring swashbuckling heroes and powerful wizards. The quest, popularized by J.R.R. Tolkein's *Lord of the Rings*, continues to be a common theme in fantasy writing. An increasingly popular subgenre is the political fantasy, where the struggles for power within an invented world predominate, and magic has a secondary role (George R.R. Martin). Alternate histories continue to thrive as writers and readers explore the “what if” of various real times. The urban fantasies of writers such as China Miéville and Tannith Lee have grown increasingly popular, featuring dark and gritty city settings and equally ambiguous characters. At the opposite end of the fantasy spectrum, high fantasy invites the reader into a world of elevated speech, rhetorical flourishes, and courtly practices. Here, readers still enjoy classic authors such as E.R. Eddison as well as newer practitioners such as Guy Gavriel Kay or Patricia Wrede. Whatever the subgenre, fantasy allows the reader to visit a new world where things are rarely as they seem, and where characters are fighting the good fight.

HISTORICAL FICTION

In the historical fiction genre, readers are usually seeking stories with a strong sense of time and place. The key appeals here are those aspects of the novel that take the reader back in time to a specific period and/or to a specific geographic location. In order to do this successfully, the authors of historical fiction often provide intricately detailed stories that are the result of extensive research. The quality of this research is important, as many readers of historical fiction are also readers of historical nonfiction. These readers will be the first to note any details that are inappropriate to the period under discussion. Many readers will dismiss an historical novel out of hand if they discover anachronisms. This attention to detail also is important in considering the author's use of language. Historical fiction readers will be put off by language that sounds to them more modern than the setting of the book. An eighteenth century maid who talks like a Valley Girl will lead many readers to close the book. One reason that these sorts of period details are so essential to the success of historical fiction is that many readers come to these stories to learn something about a particular time or place.

This educational experience is diminished if the reader is not confident about the accuracy of the story. The accrual of details in historical fiction often means that these are long works that readers can sink themselves into. Though not as common as in fantasy and crime fiction, series titles also make their appearance in the historical genre, especially in the form of family sagas (e.g., John Jakes's *North and South* series or Jean Auel's *Earth's Children* titles). Historical fiction must, by definition, be set in the past. But there is no strong consensus about how far back the tale must take place. For some readers it may relate to their own age. For a reader born in the 1980s, a novel set in the 1960s might be considered historical. The same novel read by someone born in the 1930s may not have as strong an historical feel. In most cases, it is accepted that the story needs to be set in a time prior to the period of its writing. So Tolstoy's novels are not historical fiction, but are simply older examples of contemporary fiction. It is generally accepted that the earliest examples of historical fiction are the works of Sir Walter Scott. In novels such as *Waverly*, Scott used period details and an eighteenth century setting to frame his story of love and politics during the Jacobite rebellions. Since that time, historical fiction has seen a steady readership, with specific time periods or subgenres waxing and waning to the rhythm of cultural interests. There are several popular subgenres of historical fiction, including military stories (e.g., Bernard Cornwell or C.S. Forester), with their focus on details of battles and campaigns. Historical mysteries became increasingly popular in the last quarter of the twentieth century, as readers enjoyed the period details of historical fiction blended with the elements of a crime novel (Ellis Peters, Bruce Alexander, and Anne Perry are all benchmark authors here). The early twenty-first century has seen a number of popular titles that blended history with fantastic elements, especially Diana Gabaldon's *Outlander* titles. Although not really subgenres, historical mysteries can also be subdivided by geographic location, time period, and the focus on real or fiction characters. Regardless of the specific period of interest, historical fiction readers continue to seek out the genre for its blend of detail and story.

HORROR

The horror genre is at heart about fear. Readers come to horror fiction looking for a visceral reaction to the story. While these reactions can range from a cold chill up the back of the neck to a sweat-drenched panic, to be successful, horror must induce a sense of dread in the reader. Horror fiction arises out of the Gothic novels of the late eighteenth century, in particular, the dark and fear-shrouded *Castle of Otranto* by Horace Walpole. The macabre tales of Poe and other nineteenth century novelists continued the trend. Bolstered by the popularity of horror titles in the pulp publications of the 1930s and

1940s, horror continued to build a dedicated, though perhaps limited, following. Unlike fantasy fiction, which can at times be frightening, horror fiction sustains a sense of dread throughout the entire story. The reader also has a feeling that these things could really be happening. As Joyce Saricks notes in *The Readers' Advisory Guide to Genre Fiction*, there are two paths that horror fiction generally uses to create an atmosphere of dread.^[5] The first is the psychological thriller, what Saricks calls "Storyteller Horror." Here, the terror is a reflection of a dark and menacing atmosphere that becomes increasingly oppressing as the story progresses. The characters, and the readers, are drawn into an evermore frightening situation as they move through the novel. There may or may not be physical violence involved in the resolution, but it is the overwhelming and progressive sense of fear that draws readers to these tales. The ghost stories of Peter Straub or the classic tales of H.P. Lovecraft exemplify this subgenre. The other path chosen by horror writers is the graphic and gory tale which appeals to the reader's fears of physical violence (Saricks's "Visceral Horror"). Here, the fear comes more from the actual events than from the anticipation of those events. The works of writers such as Clive Barker and John Connolly are benchmarks here. In much of horror writing, the fear of "the other" dominates. Monsters are common in horror fiction, and whether they are imagined or real, they create the chaotic events that mark the story. Unlike most other genre fiction that closes with a clear resolution to the story, horror novels often have an open ended feel. As horror has developed, some subgenres can be identified. While less popular than in earlier days (M.R. James is a classic here), the ghost story continues to have its readers (see Joe Hill, Stephen King's son). The late twentieth and early twenty-first centuries saw an increasing number of horror stories focusing on the undead, particularly vampires, though zombies and werewolves also have their followers (Ann Rice and Laurell K. Hamilton stand out here). Splatterpunk, which arose as a horror subgenre in the 1980s, is known for its extremely graphic violence, its realistic urban settings, and its grim tone (see David Schow, Jack Ketchum). The late twentieth century also saw an increasing level of eroticism in horror fiction, exemplified by some of the stories of Poppy Z. Brite or Tannith Lee, that continues to exist alongside more traditional tales of terror. Though horror readers do not make up as large a percentage of the genre audience as crime or romance readers, the demand for fear-inducing fiction is still a driving force.

ROMANCE

In 2007, statistics from the Romance Writers of America indicate that romance fiction made up about 12.9% of book sales.^[6] Like horror fiction, romance novels also arose out of the Gothic literature traditions. Here though,

the path led not toward the macabre and horrific, but to the dark castles inhabited by brooding dukes who fell hopelessly in love with young women of dubious backgrounds. These Gothic tales eventually led to historical romances by writers such as Georgette Heyer that dominated the romance market in the first half of the twentieth century and that eventually led to the contemporary romance novel. At the core, romances are the most optimistic of genre fiction. They tell the story of two people falling in love. Like crime fiction, romances follow a pattern that is consistent throughout the genre. In a typical romance, the male and female protagonists are introduced at the start of the book. In most cases, there is some source of conflict between these characters. This conflict may be personal, the result of social constraints, or have its roots elsewhere in the characters' lives. The story then deals with the overcoming of these obstacles, allowing the couple to find a measure of happiness together. In the traditional romance story, this resolution is marriage, though more contemporary romances sometimes settle for some form of committed relationship. Many readers find the commitment to traditional values of family and marriage an appealing piece of the romance genre. The happy ending is essential to the success of the story for the reader. While the positive outcome of the relationship is a primary appeal to romance readers, other appeals also draw readers to these stories. Romances generally feature strong female characters who take responsibility for their own lives and fates. This is particularly true in the work of writers such as Linda Howard and Sandra Brown, who write in the increasingly popular romantic suspense subgenre. As romances developed in the last part of the twentieth century, authors such as Nora Roberts, Karen Kingsbury and Susan Wiggs began exploring difficult societal issues, including abortion, spousal abuse, alcoholism, single parenting, and other challenging topics. These elements add another layer to the traditional romance story. Romances can vary widely across time periods and geographic settings, and readers are often drawn to particular writers for these details. Romances also vary on the amount and the graphicness of sexual content, moving from the chaste to the erotic. As societal norms have loosened, romance fiction has become more open to graphic depictions of sexuality by writers such as Bertrice Small and Rochelle Alers. In addition to these looser categories of romance fiction, there are some well-defined subgenres that attract readers. Historical romances have been an important area for many years, and continue to have a strong following. In particular, stories set in England during the Regency period are much sought after. The previously mentioned romantic suspense novels continue to command a wide audience. Lori Wick and Karen Kingsbury among others have crafted inspirational romances that feature evangelical Christian themes and stories and have a large readership, especially among readers looking for more chaste stories. The fantasy or paranormal romance also is increasingly popular in the early twenty-first century as is seen in the

interest in stories by writers such as Diana Gabaldon and Debbie Macomber. As the sales of romance novels reflect, these tales of requited love continue to inspire readers.

SCIENCE FICTION

Readers who are interested in questions of where society is going and what the future has to offer have always found much to enjoy in the science fiction genre. Throughout its history, science fiction has explored the possibilities and challenges of technology, and in particular what changes technological innovation brings to human society. Like other genre fiction writing, science fiction is shaped by cultural trends and changes. The earliest science fiction writers in the late nineteenth century, among them Jules Verne, H.G. Wells, looked at the technological advances of the industrial revolution and posited where those advances would lead. Throughout the first half of the twentieth century, science fiction writing explored the themes of space travel, exploration, and colonization, particularly in the pulp magazine of the period. As the world entered the Atomic Age, science fiction took a darker turn, and many writers produced dystopian novels of the end of human culture. The rise of computers in the last quarter of the twentieth century saw an equivalent rise in science fiction writing that looked at issues of technology and personal identity. In all cases though, science fiction uses the theme of technological advancement to explore the world. Much of science fiction writing is concerned with ideas, examining the nature of society, and the role of technology in society. There is also a strong component of science fiction writing that delves into the intricate details of science. As a result the character appeal, so common in much of genre fiction, is often less central to traditional science fiction writing. Over the years, the trend in science fiction writing has been a move from the adventure-based novels of exploration and conquest of space to philosophical stories that examine the consequences of actions in a more nuanced fashion. Some critics have speculated whether science fiction will be able to thrive as real science continues to uncover the secrets of the universe. As the elements of hard science become less important, and the more philosophic approach becomes common, character has become more central to science fiction writing, and the early twenty-first century has seen a rise in the publication of science fiction titles that concern themselves with the impact of the future not only on civilizations but also on individuals. Like the other genres, science fiction has a number of subgenres that attract readers. The space operas of Lois McMaster Bujold or Larry Niven bring together a large cast of characters and usually features themes of exploration and conquest. Space travel is also an essential part of the colonization subgenre, where alien worlds come into contact (see the novels and short fiction of Ursula K. Leguin). Post-apocalyptic tales of dark futures have already been

mentioned as has computer-centered science fiction. The cyberpunk subgenre, exemplified in the work of Bruce Sterling and William Gibson, is an offshoot of these computer-based stories, and blends dystopian views and information technology. Military science fiction such as that of David Drake or Robert Heinlein appeals to readers looking for tactics and strategy on a galactic scale. Some readers place alternative histories, for example, Harry Turtledove's *American Empire* series in the science fiction genre, particularly those that include the introduction of modern technologies into earlier days. Although real scientific work has taken much of the mystery out of the world, science fiction readers are still captivated by the genre's exploration of the possibilities and the challenges of technology.

WESTERNS

In both the traditional and the contemporary Western novel the setting is the main appeal for most readers. The open spaces and the wide views across the prairies and deserts of the American West in the work of classic Western writers such as Louis L'Amour and Zane Grey continue to attract readers. The history of the western is rooted in the dime novel tales of outlaws, mountain men, cowboys, and other denizens of the early days of the westward expansion. These stories featured tough men who often found themselves in dangerous situations, and used their skills to extricate themselves from danger. In addition to the action/adventure themes though, many westerns have an elegiac feel as well. The stories tell of the incursion of the modern world into a seemingly idyllic life on the range. The coming of the railroads, fences, and towns all become challenges to the heroes of western novels. This concept of "hero" is essential to the western. The popular western novels of the twentieth century generally featured a lone hero who finds himself fighting against evil and corruption. Often battered, but rarely broken, this hero cleans up the problem and then moves on to the next task. A strong influence from western films can be seen in many of the novels of the West. The visual nature of the films, with sweeping views becomes part of the visual scene painting of the western writers. Contemporary westerns, such as those written by Elmer Kelton and Larry McMurtry, have seen a move toward expanding the role of the hero beyond cowboys. The perspectives of Native Americans and women characters are occasionally seen, and some writers have explored social and environmental issues in their stories. In addition to the traditional western, readers can find western romances, inspirational westerns, and mysteries with strong western settings and characters, as well as novels of the contemporary west. Many librarians note a decline in the popularity of the western since its apogee in the 1960s. In the future, Westerns may come to be considered a subgenre of historical fiction. Although the circulation of westerns has declined,

there is still a dedicated body of readers looking for these tales of western adventure.

NARRATIVE NONFICTION

Although readers' advisory work has generally focused on fiction reading, the early twenty-first century saw a shift toward working with readers of narrative nonfiction as well. Narrative nonfiction blends the narrative style of fiction writing with facts, capturing characters, and telling stories with intricate plots and detailed settings. These are books that tell a story, and that are read for pleasure by a wide assortment of readers. Writers such as John McPhee, Sebastian Junger, Sue Hubbell, and Tracy Kidder are among the many prominent practitioners of this style. Like its fictional counterparts, narrative nonfiction is centered around the idea of story. All of the appeal factors that can be derived from fiction writing are applicable to narrative nonfiction. Readers in this area respond to variations in character, story, setting, language, and mood in the same way fiction readers do. The development of the structure of narrative nonfiction as a genre is still fluid at the end of the first decade of the twenty-first century. Several attempts have been made to organize the broader world of narrative nonfiction writing into more accessible, genre-like, areas. Some of these areas mirror or share characteristics with fiction genres—True Adventure, True Crime, History, Science. Other areas are not reflected in fiction writing—Food, Travel, Microhistories, Sports. Ongoing work with nonfiction readers will shape the future direction of narrative nonfiction as a genre, but given the wide readership and the interest of the publishing industry in works in this area, narrative nonfiction will continue to grow in importance in the popular reading world.

EMERGING GENRES

The late twentieth century witnessed not only an explosion in the popularity of traditional genre fiction, but also the emergence of some new directions in genre. Whether these emerging genres will stand the test of time or prove to be short-lived remains to be seen.

Chick Lit

The mid-1990s saw the development of a new type of fiction, dubbed "chick lit," that has gained acceptance as a popular genre over the past decade. Helen Fielding's *Bridget Jones's Diary* was among the first chick lit stories to attain popular success, and she has had many imitators in the years since. Although it is sometimes classed as a subgenre of romance, chick lit's themes set it apart from the romance genre. Chick lit tells the stories of the lives and loves of young, urban women who are trying to find a place for themselves in the professional world. The stories

are filled with pop culture references to hip clothing, fashion accessories, and drinks. While romantic relationships may form a part of the story, the successful resolution of relationships that is crucial to romances is not necessarily a part of a chick lit tale. Success here may as likely be dumping a boyfriend as marrying him. The story here is not about romantic accomplishment, but about a young woman learning to stand on her own. Friends play an important role in these stories as supports for the main character. A variety of urban settings spreads the appeal of chick lit across ethnic and geographic boundaries.

Slipstream

The last decade of the twentieth century produced a number of writers whose works bridged the gap between literary fiction and speculative fiction. These novels are imbued with a sense of the surreal. The settings are mainly contemporary and based in reality, but these stories manage to twist reality in ways that “simply makes you feel very strange,”^[7] as writer Bruce Sterling who coined the term “slipstream” notes. There may be occasional elements of science fiction or fantasy in these works, but these novels do not follow the usual patterns of those genres, and may not be as satisfying to a dedicated science fiction or fantasy fan. The idea of the surreal intruding on everyday life finds its roots in the magical realism of Latin American fiction and even in earlier works that created a feeling of unease in the reader. Sterling’s essay goes on to question whether slipstream will succeed as a genre, but thus far it continues to gain readership. In addition to Sterling, other notable slipstream authors include, Jonathan Lethem, Paul Auster, Aimee Bender, and Cory Doctorow.

Street Lit/Urban Fiction

The burgeoning street lit genre tells hard-edged stories of African American life in bleak urban settings. Street lit arises out of the 1970s autobiographical fiction of drug dealing and prison life by authors such as Donald Goines and Iceberg Slim as well as the tradition of African American romance and erotica. Contemporary street lit features all the elements of “gangsta” culture—flashy jewelry, big cars, drugs, prostitution, and guns. Like the emerging chick lit genre, the stories feature a lot of name-checking of expensive or hip brands and pop culture trends. The stories tend to be graphic in language, violence, and sexuality. Street lit is notable for featuring strong protagonists, both male and female. There has been some controversy over the genre, with some condemning the romanticization of criminal culture and others noting the moral lessons that can be drawn from the stories. Street lit seems to be diverging into two main streams. The first are the gangsta novels that center around drugs, money, and guns. The second are the more relationship-centered stories, still set in the violent street world, but focusing more on romantic issues. Benchmark authors here include Chunichi, K’wan, and Nikki Turner.

GENRE OR READING INTEREST

In addition to looking at genre as a way to define popular reading tastes and areas, it can also be useful to consider divisions that are more logically termed “reading interests” (the phrase used for these areas in Libraries Unlimited’s Genreflecting series). Reading interest is a broader term, and identifies a theme-related group of books or authors whose writings can be found in many genres. Three major reading interests to examine are Inspirational, African American, and Multicultural. In each of these areas, readers and librarians will find authors who write stories in most if not all of the traditional and emerging genres. What ties these disparate authors and their books together in the mind of readers, librarians, and publishers is an overarching theme. In the case of inspirational fiction it is the evangelical Christian outlook that is at the heart of the story, regardless if it is a mystery, romance, or legal thriller. With African American fiction, the unifying theme is the story of the lives of an ethnic minority in the broader American culture. Multicultural fiction details of the lives and concerns of a broad range of ethnic groups across the world, either in their own countries or as immigrants to a new society. In all these cases, the application of a genre label would be difficult since each of these reading interests encompasses the entire world of genre fiction.

CROSS-GENRE PHENOMENON

There has always been a certain amount of cross pollination between genres. Historical mysteries may appeal to both readers interested in crime fiction as well as readers with an interest in history. Similarly, many readers of Regency romances enjoy the period details as much as the satisfaction of a good love story. However, the trend toward cross-genre writing has exploded in the early twenty-first century. The popular success of titles such as Mary Doria Russell’s *The Sparrow* (which uses a very literary style to explore space travel and the issues of alien encounters and colonization) or Diana Gabaldon’s *Outlander* series (which blends time travel, romance, and history) have exposed many readers to styles of writing they would not necessarily have tried otherwise. Blending of paranormal elements usually found in horror fiction with crime fiction, romances, and chick lit tales has become common. For librarians, the cross genre publishing phenomenon has raised certain challenges. One difficulty that arises is how to categorize a particular book for a specific reader. Is a mystery that features a vampire detective more appealing to a crime fiction reader or a horror or fantasy reader? Another concern is the tendency of some readers to use genre not as a system of classification but as a method to reject titles that they do not wish to read. Assigning *The Sparrow* to the science fiction genre may deter some readers who aver that they never read science

fiction. Ursula Le Guin notes that it is when genre begins to be used to make value judgments about a particular work that the system leads to “arbitrary hierarchies” that promote “ignorance and arrogance.”^[1] The cross genre trend has led to renewed discussion in the library profession about the value of separating out genres in the fiction collection (see p. 33–38).^[2] Decisions on what genres to separate out from the main fiction collection and how to assign cross genre titles to a particular area will continue to be debated as the trend toward blending genres grows.

CONCLUSION

An understanding of fiction genres and their characteristics enables librarians to organize and locate materials that will meet the needs of their users. Awareness of emerging genres and trends in popular reading tastes will continue to be important for collectors, readers’ advisors, and other library staff working with popular fiction collections.

Precision and Recall [ELIS Classic]

F. W. Lancaster

Graduate School of Library and Information Science, University of Illinois at Urbana-Champaign, Urbana, Illinois, U.S.A.

Abstract

F.W. Lancaster's work has been immensely influential in library and information science. He has written on indexing and information system evaluation, and has been looked to as a pioneer in many areas. Here he describes precision and recall, the two most fundamental and widespread measures of information retrieval effectiveness.

—*ELIS Classic*, from 1978

INTRODUCTION

The terms “precision” and “recall” refer to measures that are commonly used to evaluate the performance of a literature search, especially a search conducted in some type of information retrieval system. These measures are probably best explained in the context of the well-known 2×2 table of search results, as illustrated in Table 1. When a search is conducted in most information retrieval systems, the system divides up the document collection into two parts. The documents that match the search strategy used to interrogate the system are *retrieved* ($a + b$), and all the documents that fail to match this strategy are *not retrieved* ($c + d$). This dichotomous partitioning of the document collection may be regarded as a form of system relevance prediction. The system, in a sense, predicts that certain documents are likely to be relevant and others are likely not to be relevant. It retrieves the former and holds back the latter.

OVERVIEW

In almost all situations, the number of documents retrieved by a search will be quite small in relation to the total collection size. Put differently, in almost all searches, $a + b$ will be quite small but $c + d$, the number of items not retrieved, will be very large. A search might, for example, retrieve 80 document references from a total file of 500,000 references. In this case, $a + b = 80$, while $c + d = 499,920$.

The other dimension of the 2×2 table relates to the relevance decisions of the system user (i.e., the person for whom the search is conducted). A perfect search would retrieve all the documents in the database that the user judges to be relevant ($a + c$) and would not retrieve any that he judges not to be relevant ($b + d$). In this case, there is perfect coincidence between the user relevance assessments and the system relevance predictions. That is, $b = 0$ and $c = 0$. We would say that this search has achieved 100% recall and 100% precision.

Recall relates to the ability of the system to retrieve relevant documents and *precision* relates to its ability not to retrieve irrelevant documents. The degree of recall achieved in a search, and the degree of precision achieved in a search, may both be expressed as ratios. The *recall ratio* is defined as

$$\frac{\text{Number of relevant documents retrieved}}{\text{Total number of relevant documents in the collection}} \times 100$$

In terms of Table 1, the recall ratio is

$$\frac{a}{a + c}$$

The *precision ratio* is defined as

$$\frac{\text{Number of relevant documents retrieved}}{\text{Total number of documents retrieved}} \times 100$$

In terms of Table 1, the precision ratio is

$$\frac{a}{a + b}$$

The precision ratio and the recall ratio, used jointly, express the filtering capacity of the system: its ability to let through what we want and hold back what we don't want. Neither one on its own gives a complete picture of the success of a search because, clearly, it would always be possible to get 100% recall if we retrieved enough of the total collection; if we retrieved the entire collection ($a + b + c + d$), we would certainly achieve 100% recall. Unfortunately, however, precision would be extremely low in this situation because, for any typical request, the great majority of the items in the collection will not be relevant.

The precision ratio may be viewed as a type of cost factor. It is a cost factor in user time—the time required to

Table 1 2×2 Table of results of a literature search

System relevance prediction	User relevance decisions		
	Relevant	Not relevant	Total
Retrieved	a	b	$a + b$
Not retrieved	c	d	$c + d$
Total	$a + c$	$b + d$	$a + b + c + d$

separate the relevant citations from the irrelevant ones in the output of a search. Consider, as an illustration, a search request for which there are 20 relevant documents in a particular database. Suppose that one uses three different search strategies to interrogate the system and that each strategy retrieves 15 of the 20 relevant items (i.e., recall is 75%). In the first search, the total number of items retrieved is 30; in the second, it is 60; and in the third, it is 150. The precision ratio in these three searches is 50%, 25%, and 10%, respectively. In the first search, the user has to examine only 30 citations to find the 15 of relevance; in the second he must examine 60; and in the third, 150. All other things being equal, it will take him longer to separate the relevant from the irrelevant in the second search and considerably longer in the third. It is in this sense that we can regard the precision ratio as a measure of user effort or cost. A search that achieves 75% recall at 50% precision is more efficient than one that achieves 75% recall at 25% precision, and this is more efficient than one that achieves 75% recall at 10% precision.

As stated earlier, these ratios measure the degree of coincidence between the user relevance assessments and the system relevance predictions. In a perfect search, these will exactly coincide. Unfortunately, such perfect searches are relatively rare. We are more likely to get a situation in which there is partial coincidence between the set $a + c$ and the set $a + b$, as shown in Fig. 1. In this diagram, the total collection is represented by the solid rectangle and the set of items retrieved by the dotted rectangle. The hypothetical, but very typical, search has retrieved most, but not all, of the relevant documents and has avoided retrieval of most, but not all, of the irrelevant documents.

Recall and precision tend to be related inversely. By this we mean that when we broaden a search, to achieve better recall, precision will tend to go down. Conversely, when we narrow the scope of a search, in order to improve

**Fig. 1** Results of a typical search in a retrieval system.

its precision, recall will tend to deteriorate. For a particular group of, say, 50 requests, we could conduct each search at a number of different levels, from an extremely broad search designed to get very high recall, to an extremely narrow one, designed to get high precision. If we derived recall and precision ratios for each of these search approaches, we could reduce the results to a plot of recall versus precision. The resulting plot would look something like that of Fig. 2. It represents the average of the recall and precision ratios for all 50 searches, with each search being conducted at four different “levels.” It can be seen that when the searches are conducted very generally (point A), a very high recall of around 90% is achieved; the precision, however, is very low. When, on the other hand, the searches are made very specific, a high-precision, low-recall result (point D) is achieved. The points B and C represent compromise strategies between these two extremes.

The curve of Fig. 2 represents the *average* of the results for 50 searches when each search is deliberately conducted at four different levels. But, in this situation, as in others, averages may be quite misleading. The performance figures for the individual searches are unlikely to fall on this curve. In fact, they are likely to be widely scattered, as shown in Fig. 3. Here we can see some very good results (top right-hand corner of the plot), some very poor results (bottom left-hand corner), some high recall–low precision results, some high precision–low recall results, and some completely middle-of-the-road results. When we average out all of these, we arrive at average performance figures and an average performance curve, A–D.

Recall and precision ratios are two important measures that can be used in the evaluation of an information retrieval system. Their major value lies in the fact that they can be used to determine under what conditions the system seems to operate best. Consider Fig. 3 again. What we really want to know is why some searches have produced very good results and some very poor results. In

**Fig. 2** Typical plot of recall versus precision.

Fig. 3 Scatter diagram of search results.

other words, “what makes a good search good” and “what makes a bad search bad”? One way of approaching an answer to this question is to divide up all the searches according to various characteristics and to produce a family of curves for the various sets of searches thus created. In Fig. 4, we see the average performance curves for three groups of searches. Clearly, Group 1 has produced the best results and Group 3, the worst. The curves shown in Fig. 4 may represent searches conducted in different subject fields, searches conducted by different processing centers, searches conducted for different types of users, searches conducted for requests arriving in various ways (by mail, by telephone, by personal visit), and so on.

An analysis of this type might indicate weaknesses in the system and ways in which the performance might be improved. For example, if the Group 3 curve represents searches in a particular subject area, these poor results might indicate inadequacies in the vocabulary of the

Fig. 4 Family of curves representing results for groups of searches of different “types.”

system in this subject field. The evaluation has pinpointed this weakness and thus allows us to take appropriate corrective action. It should be pointed out, however, that we are likely to need a fairly large number of searches (many more than 50) to conduct, with any level of statistical confidence, the type of comparison exemplified by Fig. 4.

Recall and precision ratios have another important use. Each ratio is likely to indicate a certain number of failures and this permits us to conduct an analysis to determine why these failures occurred. To take a simple example, suppose that a particular search has performed as follows:

1. $7/10 = 70\%$ recall
2. $7/28 = 25\%$ precision

These results indicate 3 recall failures (instances in which a relevant item was not retrieved by the search) and 21 precision failures (instances in which irrelevant items were retrieved by the search), and these failures must be analyzed to determine why they occurred. Failure analysis of this type is the diagnostic element in an evaluation program. It is the most important part of the entire evaluation activity. Failure analysis requires an examination of the document involved, how it was indexed, the request statement, the search strategy, and the vocabulary of the system. The objective is to determine why the failure occurred and to attribute the failure to the appropriate component of the total retrieval system (the indexing, the search strategy, the vocabulary, or the user-system interface).

So far in this article, we have assumed that it is relatively simple to obtain recall and precision ratios for a search in a retrieval system. It is relatively easy to obtain a precision ratio for a search, but, it is not at all easy to measure recall. Consider another 2×2 table, Table 2, this time with some hypothetical results entered. Some of the results in this table are directly observable, others can be obtained through the cooperation of the requester, and some can only be estimated.

The database represented in this table contains 500,000 items, and this hypothetical search has retrieved 50 items and has not retrieved 499,950. This is a typical result. For any search in a retrieval system, the great majority of the items in the collection are not retrieved. To obtain a precision ratio for the search, we need to discover how many of the 50 items retrieved are “relevant.” We can obtain this

Table 2 Results of a hypothetical search in an information retrieval system

System relevance prediction	User relevance decisions		
	Relevant	Not relevant	Total
Retrieved	10	40	50
Not retrieved	5	499,945	499,950
Total	15	499,985	500,000

figure by submitting these items to the person requesting the search and asking him to assess their relevance to the information need that prompted the request to the system. In this hypothetical case, he judges only 10 to be relevant. The precision ratio is thus 10/50, or 20%. We have assumed here that it is the requester who should make these relevance assessments. Not everyone accepts this assumption, however, and some would have relevance assessments made by an independent observer or possibly a jury of such observers.

We are still left with the problem of estimating recall, and this is not particularly easy. To establish recall, we need to determine how many of the documents not retrieved by the search are, in fact, relevant to the search request. There is only one way of determining absolute recall for a search and that would involve the examination of each and every item not retrieved. This is an impossible task in any but a very small, experimental situation. In the case of the search represented in Table 2, 499,950 documents would need to be examined. Random sampling does not improve the situation very much. In the case of this hypothetical search, we would need to examine a sample of $499,950/5$ items, almost 100,000, in order to have any chance of finding even one relevant item purely at random.

Since it is virtually impossible to determine absolute recall, we must usually be satisfied with an estimate of recall. The most satisfactory of these is to base the recall estimate on some subset of documents known to exist in the database and known to be relevant. The situation is represented in Fig. 5. For any request R , the collection I contains a set of documents A that the initiator of the request would judge relevant if he saw them. That is, they are the set $a + c$ of Table 1. Unfortunately, we do not know the identity of the documents in this set. For a very large collection, we will never know it. We can, however, estimate recall on the basis of a subset $A1$ of the set A . The subset $A1$ consists of a group of documents that we know to be relevant and we know to exist in the database. This subset could consist of relevant documents known by the requester before the search is conducted, it could consist of items found by a parallel search in one or more other indexes (e.g., printed indexes) and judged relevant by the requester, or it could be derived from a combination of these two sources. However we arrive at it, the recall ratio

Fig. 5 Method of estimating recall by subset of relevant documents known to exist in the database.

of the search is estimated on the basis of the number of this subset $A1$ that are retrieved. To take a very simple example, suppose that the subset $A1$ consists of 3 documents known to be relevant and known to be in the collection. The search retrieves 2 of the 3 and our recall estimate is, therefore, 66%. In the case of the hypothetical search of Table 2, we know that 10 relevant documents have been retrieved. Our recall estimate indicates that 10 is approximately 66% of the total of relevant documents in the database. Our estimate of the number of relevant documents missed, then, is 5.

The subset $A1$ is the *recall base* by which we estimate the recall ratio for a search. It is obvious that with very small recall bases we can have little statistical confidence in the recall estimate for a single search. But when we apply this technique to a large number of searches, we can create quite a large composite recall base and, as shown by Shumway,^[1] we can achieve quite a high degree of confidence in the results for the entire set of searches or for large groups of these searches. This technique was used by Lancaster in the largest evaluation so far conducted.^[2] This study was an evaluation of MEDLARS, the computer-based system of the National Library of Medicine. Some 300 searches were used in this study, and the combined recall base for these searches consisted of almost 2,000 known relevant documents.

DIFFERING REQUIREMENTS FOR RECALL AND PRECISION

Not everyone needs high recall all of the time. Different users will have different requirements for recall and precision, and a particular individual will have different requirements at different times. The precision tolerance of the user is likely to be directly related to his recall requirements. At one end of the spectrum, we have the individual who is writing a book, preparing a review article, or beginning a long-term research project. He is likely to want a comprehensive (high recall) search, and he may tolerate a fairly low precision in order to assure himself that he has not missed anything of importance. At the other end, we have the typical user of, say, an industrial information service who needs a few recent articles on a subject and needs them right away. This individual does not need high recall, but he will expect high precision in the search results. Other individuals may prefer a compromise; they would like a "reasonable" level of recall at an "acceptable" level of precision.

It seems rather pointless to use the recall ratio as a measure of the success of a search in which high recall is unimportant. This has led some writers to suggest the use of some measure of proportional recall (or relative recall) in which the success of the search is expressed in terms of the number of relevant documents retrieved over the number of relevant documents wanted by the requester. For example,

the requester specifies that he needs five relevant documents but the search retrieves only three. The proportional recall ratio is, therefore, three-fifths or 60%. This measure, while attractive on the surface, is rather artificial in that very few requesters will be able to specify in advance just how many documents they want from the system.

Another limitation of the recall ratio is that it assumes, more or less, that all relevant documents have approximately equal value. This is not always true. A search may retrieve 5 relevant documents and miss 10 (recall ratio = 33%) but the 5 retrieved may be much better than the 10 missed. They could, for example, be more up to date and might in fact make the other 10 items completely redundant. The recall ratio, while important, must therefore be used with some caution in the evaluation of information services.

ALTERNATIVE PERFORMANCE MEASURES

The 2×2 table (Table 1) contains all the data that we really need to know about a search in a retrieval system for evaluation purposes. One way of expressing the results of this table is by the recall ratio and the precision ratio, used jointly. But there are several other measures of performance that can be derived from this table, and there are various ways in which these results can be presented. Before we mention some alternative measures, it may be desirable to give some names to the various cells of Table 1. The set a we can refer to as the *hits*, the set c as the *misses*, the set b as the *noise* (in the communications sense), and d as the set *correctly rejected*.

From Table 1, all of the following measures can be derived:

- $a/(a + c)$ The *recall ratio*, also known as the *hit rate*. The measure was apparently first suggested by Perry, who referred to it as the *recall factor*.^[3] Swets calls it the *conditional probability of a hit*.^[4] Goffman and Newill have called it *sensitivity*.^[5]
- $c/(a + c)$ This is the complement of recall. Fairthorne has called it a *snobbery ratio*.^[6] Swets terms it *conditional probability of a miss*.
- $a/(a + b)$ This is the *precision ratio*, sometimes referred to as the *relevance ratio*. Again, Perry seems to have introduced the measure.^[3] Perry called it the *pertinency factor*. Others have referred to it as an *acceptance rate*.
- $b/(a + b)$ This is the complement of the precision ratio, called, by Perry, the *noise factor*.
- $b/(b + d)$ This measure seems to have been first suggested by Swets, who referred to it as the *conditional probability of a false drop*.^[4] Cleverdon et al. have since named it the *fallout ratio*.^[7] It has also been referred to as *discard*.
- $d/(b + d)$ The complement of *fallout*. Goffman and Newill have called it *specificity*.^[5] Swets names it the *conditional probability of a correct rejection*.

Each one of these measures can be referred to as a *single measure* of merit for a search. When two measures are used together (as in a plot of recall versus precision or recall versus fallout), this has been referred to as a *twin variable measure*. When an attempt is made to combine two of these separate measures into a single measure (e.g., one reflecting both recall and precision), the result is known as a *composite measure* or, possibly, a *single figure of merit*.

These measures are appropriate for use with a retrieval system that merely divides a collection into two parts, those items retrieved and those not retrieved by a particular search. But certain systems will do more than this. They will generate a "ranked output" of documents in order of probable relevance to a request. Ranking systems should be evaluated in a somewhat different way because here we need an indication of the success of the ranking procedure. Various measures that have been applied to ranking systems include *rank recall*, *log precision*, *normalized recall*, and *normalized precision*. These measures, introduced by Salton, essentially compare the actual ranking achieved by the system with an ideal ranking.^[8] That is, the measures reflect the degree to which the ranking matches the ideal situation.

CONCLUSION

Rather complete discussions of evaluation measures, methods of averaging results, and methods of presenting results of retrieval tests have been provided by Keen^[9,10] and by Robertson.^[11,12] Recall ratios and precision ratios have been the measures most used in evaluations of information retrieval systems. These measures were popularized by Cleverdon in the ASLIB Cranfield Project.^[13] Many other writers, however, have presented reasons why other measures may be regarded as more accurate or more informative. Robertson's paper provides a useful analysis of the pros and cons of the various measures that have been proposed or used.

Presidential Libraries

Sharon Fawcett

Office of Presidential Libraries, National Archives and Records Administration, College Park, Maryland, U.S.A.

Abstract

The National Archives and Records Administration (NARA) administers a nationwide network of Presidential libraries beginning with the 31st President of the United States, Herbert Hoover. These are not traditional libraries, but rather repositories for preserving and making accessible the papers, records, and other historical materials of U.S. Presidents. When a President leaves office, NARA establishes a Presidential project until a new Presidential library is built and transferred to the Government. Presidential libraries and museums are great treasures of our nation's history. They are important sources for historians and other researchers studying our presidents and our history. In addition to archiving and preserving presidential papers and objects, presidential libraries and museums bring history to millions of visitors from around the world.

BRIEF HISTORY OF THE PRESIDENTIAL LIBRARY SYSTEM

Sixty years ago, Franklin D. Roosevelt proposed creating a Presidential Library that would be part of an institution whose growth he had shepherded—the National Archives. Roosevelt suggested a creative approach—he would donate the land, build the library with private funding, and then give the library and his papers to the National Archives. On June 30, 1941, as the war in Europe threatened democracy, Roosevelt dedicated his library at Hyde Park. His words of dedication express as well today as then the importance of records in the nation's history and the nation's future.

To bring together the records of the past and to house them in buildings where they will be preserved for the use of men and women in the future, a Nation must believe in three things.

It must believe in the past.

It must believe in the future.

It must, above all, believe in the capacity of its own people so to learn from the past that they can gain judgment in creating their own future.^[1]

The Roosevelt Library is the only Presidential Library built, dedicated, and used while the president was still in office. It became the model for the Presidential Library system. Privately constructed and donated to the government, Presidential Libraries provide extensive services for their researchers, an expansive collection of presidential materials, and incorporate a museum experience for hundreds of thousands of visitors each year. Geographically

dispersed around the country, Presidential Libraries allow more students and the public to learn about the election process; how government works; leadership, decision making, and the role of the presidency; and historical events that have taken place in much of the twentieth century.

In 1952, President Truman, deploring the scattering of presidential papers in the past, stated “[the President's papers] ought to be accessible in one place...where the scholars and archivists can get to them without difficulty. I hope we will have that in the future.” He went on to say that he wanted the “state papers of President Roosevelt and myself properly cared for.”^[2] Originally, Truman considered depositing his papers at the National Archives, in Washington, DC, but by 1950, he decided on a Presidential Library in his hometown of Independence, Missouri. Truman strongly believed that Presidential Libraries were not to be monuments to a president but centers for the study of the presidency. The Truman Institute, established to build and support the library, has a long history of sponsoring intellectual exchanges through conferences and the Truman Grants program for the study of the presidency.

Dwight D. Eisenhower's clear support of the development of a library at the site of the already established Eisenhower Museum in Abilene, Kansas, prompted Congress to pass The Presidential Libraries Act of 1955 (44 U.S.C. § 2108). The legislation had full bipartisan support, and was hailed by scholars and educators. This act provided continuing legal authority for the government to accept the gift of a Presidential Library without seeking legislative authority for each new library.

President Hoover had originally given his papers to Stanford University, but responded favorably to a request of a citizens committee from his hometown for the

development of a library in West Branch, Iowa. His library became the third added to the system in 1962. The Eisenhower Library was also opened in 1962, and a pattern, which has remained unbroken, was established.

Over time, however, the venue for a Presidential Library shifted from the president's hometown, to larger metropolitan areas or a university campus. The Lyndon B. Johnson Presidential Library and Museum became the first Presidential Library located on a university campus. President Johnson sought to place his library in a university environment convenient for students and faculty where materials housed in the library could be used to promote the study of history, economics, political science, public affairs, and numerous other academic pursuits. Along with building the library, the Lyndon Baines Johnson Foundation established to provide additional support for the library also supports the LBJ School of Public Affairs located next door to the library.

This has meant that this remarkable public-private partnership that builds and supports the libraries has often expanded into three- and even four-way partnerships, as the library foundation, the university, and the local community come together to build a presidential center that can be turned over to the government. The Presidential Libraries Act of 1955 presciently enabled this by authorizing the government to enter into agreements with any state or political subdivision, universities and institutions of higher learning, and institute or foundation for the purposes of using land, buildings, and equipment for a Presidential Archival Depository. The John F. Kennedy Library is adjacent to the University of Massachusetts; the Lyndon B. Johnson Library and Museum is on the campus of the University of Texas at Austin; the Gerald Ford Library is at the University of Michigan; the Jimmy Carter Library is near the campus of Emory University; the George Bush Library is part of Texas A&M University; and the William Clinton Library will be affiliated with the University of Arkansas at Little Rock.

Overseeing these institutions for the National Archives and Records Administration (NARA) is the Office of Presidential Libraries established as a permanent part of NARA in 1964. Until then, the functions of supervision, coordination, and administration of Presidential Libraries had been handled directly out of the office of the Archivist of the United States. Herman Kahn, who had been the director of the Roosevelt Library, became the first Assistant Archivist for Presidential Libraries. His job was to establish and coordinate policies with regard to Presidential Libraries, including programs for acquisition, preservation, and use of historical materials appropriate for deposit in the Presidential Libraries, and to maintain liaison with the incumbent administration and with officials of former administrations with regard to organization, storage, and reference service on presidential papers and other historical materials. The current Assistant Archivist for Presidential Libraries, appointed in November 2001, is

Richard Claypoole who now oversees a system of 10 Presidential Libraries, the Clinton Presidential Project, the Nixon Presidential Materials Staff, and the Presidential Materials Staff.

In 1986, Congress passed various amendments to the 1955 Presidential Libraries Act to reduce the costs of operating Presidential Libraries. 44 U.S.C. § 2112 requires that an endowment equal to 20% of the cost of the building be transferred to the government at the time the library is turned over to the government. Libraries larger than 70,000 square feet are to be accompanied by an endowment that increases geometrically in accordance with the size of the building. The George H.W. Bush Library is the first library required to have an endowment. On the day the Bush Library was dedicated, the Bush Foundation presented a check for \$4 million to the National Archives Trust Fund. Interest on the endowment is now used to offset part of the cost of operating the library. The act also required the Archivist to promulgate architectural and design standards for the preservation of materials and the inclusion of adequate research facilities. Architectural and design standards for Presidential Libraries address program and siting requirements and standards for structures, security, fire and life safety, lighting, electrical, and HVAC design.

The 1986 act did not change the requirement that the Archivist submit a written report to Congress prior to accepting a library, but it did set forth the specific information required in the report. The Archivist may not accept the library until the expiration of a period of 60 days of continuous session of Congress beginning on the day the Archivist transmits the report. The report must include:

- A description of the proposed gift
- A statement specifying the total cost and the amount to be deposited in an endowment
- A general description of any papers, documents, or historical materials proposed to be deposited in the library
- An estimate of the increase in the total annual cost to the United States of maintaining, operating, and protecting the depository
- A certification that the depository and the equipment therein will comply with the standards promulgated by the Archivist

PRESIDENTIAL MATERIALS

Throughout the eighteenth, nineteenth, and well into the twentieth century, no one questioned the private ownership of presidential papers by the president. Former presidents could donate them to a library or archives, or not, as they saw fit. Fortunately, many presidential papers were donated and are available for historical research

today. However, many were accidentally or purposely destroyed. Biographers of George Washington snipped out pages of Washington's diaries. Chester Arthur burned his papers. Former presidents and their families exercised considerable discretion in what they donated resulting in selective donation and selective destruction. One very powerful reason the National Archives wanted libraries built and given to the National Archives was that the donation of a library meant the National Archives would also receive the president's papers. In its time, this system of donation worked very well. Although there was nothing mandatory in the legislation for Presidential Libraries requiring that presidents systematically preserve their presidential papers, the legislation assured a president who donated his materials to the National Archives that the integrity of his papers would be preserved. The papers would be cared for by a professional archival staff and made available to all as historical records.

The handling of presidential materials began to change again with President Nixon's resignation in 1974. Congress enacted the Presidential Recordings and Materials Preservation Act (PRMPA; 44 U.S.C. § 2111) to ensure that no evidence in President Nixon's papers, tapes, or other historical material relating to Watergate would be destroyed. The PRMPA seized the Nixon presidential materials and gave the National Archives and Records Service, now the NARA, legal custody and control over them.

Historians, journalists, and Congress now raised serious questions about the ownership of presidential materials, suggesting instead they be treated as government records. PRMPA had established the National Study Commission on Records and Documents of Federal Officials to explore topics of ownership, control, disposition, and preservation of historic materials. The report of the commission, completed in March 1977, made two basic recommendations:

1. All documentary materials received or made by federal officials in discharge of their official duties should be considered the property of the United States.
2. Federal officials should be given the prerogative to control access to their materials up to 15 years after the end of their federal service.

In 1978, Congress acted on the report and passed the Presidential Records Act (44 U.S.C. § 2201-2207). This act created and defined a new category of records—presidential records—and established the terms of access to these records. The act clearly established that these records are owned by the United States. After conclusion of a president's tenure, the custody of presidential records is transferred to the Archivist of the United States. The former president retains the right to impose specific restrictions outlined in the Presidential Records Act statute

on the records until 12 years after he has left office. Executive Order 13233 signed by President George W. Bush outlines a process for notification and review for executive privilege of presidential records proposed for opening.

Government archivists and curators preserve, process, and provide access to the presidential materials in their care. The process for providing access to donated historical materials and the process for providing access to presidential records vary somewhat in implementation because of the statutory and regulatory requirements. However, the mission of the government staff in each library is the same—to preserve and process the materials, and to provide access as fully and promptly as the law or deed and resources permit.

The 10 Presidential Libraries, the Nixon Presidential Materials Staff, and the Clinton Presidential Materials Project maintain more than 400 million pages of textual materials; more than 24 million photographs; 14.5 million feet of motion picture film; 103,000 hours of disc, audio-tape, and videotape recordings; nearly 500,000 museum objects; and 40 million e-mail messages. In addition, the Clinton Presidential Materials Project has available on its website (<http://www.clinton.archives.gov>), four snapshots of the Clinton White House website.

The most important materials in each library are those the president and his staff create in the course of their official duties. In recently established Presidential Libraries, these documents can also be in electronic form. Researchers find that each library contains a rich audiovisual and photographic record of a president at work. Taken together, these historical materials form the substantive record of public policy in each administration. Libraries also house numerous museum objects including family heirlooms, items collected by the president or his family, campaign memorabilia, awards, and the many gifts given to the president by American citizens and foreign dignitaries. The latter include Head of State gifts under The Foreign Gifts and Decorations Act (22 U.S.C. § 264), and gifts received by the president from private citizens and accepted by him for eventual deposit in his presidential library (44 U.S.C. § 2111-2112). These gifts range in type from homemade items to valuable works of art. Curators in Presidential Libraries and in other museums throughout the country draw upon these collections for historical exhibits.

Other significant holdings include the personal papers and historical materials donated by individuals associated with the president. These individuals may include cabinet officials, envoys to foreign governments, political party associates, and the president's family and personal friends. Several libraries have undertaken oral history programs that have produced significant tape-recorded memoirs. A third body of materials comprises the papers accumulated by the president prior to, and following, his presidency. Such collections include documents relating to Franklin Roosevelt's tenure as Governor of New York and Dwight Eisenhower's long military career.

Each of the libraries has available on its website detailed information about their holdings. Many also provide copies of significant documents, photographs, and oral histories from their collections online. To access library websites, visit <http://www.archives.gov> and click on “Presidential Libraries” for links to each website.

Many historians, educators, and other users have offered their testimonials on the value of Presidential Libraries and the dedicated staff that preserve, process, and assist them in using the materials. Countless forwards to well-known historical works over the past 50 years refer to the importance of these materials for exploring and understanding historical themes and issues of our time. In a recent *Washington Times* article (2/28/00), the reporter noted that “As far as scholars, educators and the U.S. government are concerned, the libraries are among the most important research sites in the United States.” In the same article, Page Miller, former director of the National Coordinating Committee for the Promotion of History, is quoted saying, “All you have to do is check the footnotes of major prize-winning books and monographs dealing with presidents and you’ll see they all reference presidential libraries.” Anna Nelson, a long-time user of archives, has found that “in all these presidential libraries the archivists are splendid,” a view widely shared by other professionals who use the libraries.

The materials in Presidential Libraries are among this nation’s most important documents. Presidential records are often open for research long before the records of other departments and agencies of government are even transferred to the National Archives. Political scientists study the different approaches and processes used by presidents to govern, and then make recommendations to new presidents on what works and does not work. Economists study the impact of presidential decisions on economic indicators and project what will happen in the future. The media searches for examples from our past to inform the public about current events. Hundreds of thousands of children visit libraries each year to learn about how presidents make decisions, how laws are passed, how wars were fought, how our civil rights have been ensured, and how their ancestors lived. More than 1 million visitors each year view the human drama of the presidency through the power of objects and documents displayed in the libraries.

PUBLIC AND EDUCATIONAL PROGRAMS

Each library offers various public and educational programs designed to give visitors a better understanding of the president, the institution of the presidency, and the American political system as a whole. Exhibits, conferences, and lectures funded by privately endowed library foundations are among the special events that help to define a library, and enhance its role as a

repository and cultural institution. Museum exhibits use library holdings to depict the stages of a president’s life, the important policy decisions of his administration, and the various world and national events that occurred during his term.

Libraries work with educators to encourage the use of primary source materials by students, and sponsor public lectures, film series, and other events of historical or current interest. Conferences are another way in which the libraries serve the public and examine various topics ranging from public affairs and domestic policy to foreign affairs and world wars.

In 1973, James B. Rhoads, then Archivist of the United States, told an education symposium at the Lyndon Baines Johnson Library, “Presidential Libraries would be fulfilling their purpose if they did nothing more than preserve and provide access to the papers they contain. . .but their charters are broad and their possibilities for service are unlimited.” However broad their charters may be, the libraries face limitations imposed by financial reality. Taxpayers are under no obligation to fund a temporary exhibit on the Civil War, a conference on civil rights, or educational efforts aimed at high school students, admirable and useful as these undeniably are to the public. These efforts are funded by the libraries’ support organizations, which constitute much of the financial support received by the Presidential Libraries. Congressionally appropriated funds cover many of the personnel costs; program costs, such as collections maintenance, preservation, and access to records; building operations and maintenance; and repair and restoration. In 2001, actual obligations from appropriated funds totaled nearly \$40 million for the Presidential Library system.

LIST OF PRESIDENTIAL LIBRARIES

- Dwight D. Eisenhower Library
200 SE 4th Street
Abilene, KS 67410-2900
- Franklin D. Roosevelt
4079 Albany Post Road
Hyde Park, NY 12538-1999
- George Bush Library
1000 George Bush Drive, West
College Station, TX 77845
- Gerald R. Ford Library
1000 Beal Street
Ann Arbor, MI 48109-2114
- Gerald R. Ford Museum
303 Pearl Street, NW
Grand Rapids, MI 49504-5353
- Herbert Hoover Library
210 Parkside Drive
P.O. Box 488
West Branch, IA 52358-0488

Harry S. Truman Library
500 West U.S. Highway 24
Independence, MO 64050-1798
John Fitzgerald Kennedy Library
Columbia Point
Boston, MA 02125-3398
Jimmy Carter Library
441 Freedom Parkway
Atlanta, GA 30307-1498
Lyndon Baines Johnson Library
2313 Red River Street
Austin, TX 78705-5702
Nixon Presidential Materials Staff
8601 Adelphi Road, Room 1320
College Park, MD 20740-6001
Presidential Materials Staff
700 Pennsylvania Avenue, NW
Washington, DC 20408-0001

Ronald Reagan Library
40 Presidential Drive
Simi Valley, CA 93065-0699
William J. Clinton Presidential Materials Project
1000 LaHarpe Boulevard
Little Rock, AK 72201

Primary Records: Future Prospects [*ELIS Classic*]

G. Thomas Tanselle

Vice President, John Simon Guggenheim Memorial Foundation, New York, New York, U.S.A.

Abstract

G.T. Tanselle probes deeply into the nature of primary records. He addresses many contextual questions about their future prospects in the light of current trends to microfilm and digitize documents and destroy pre-existing versions of them.

—*ELIS Classic*, from 2003

INTRODUCTION

When one speaks of “the future of primary records,” there are at least four questions implicit in the phrase. One is, “Will people in the future have any interest in primary records?” An assumption that records of some kind will be needed leads to a second question, “What will be the form of the primary records that are created in the future?” A third question, looking backward to earlier records, is, “Will the primary records created in the past have a future usefulness as objects from the past?” This question asks, in other words, whether the perceived content of earlier records will be transferred to new forms employing the same technology as the newer records; and, if so, whether there is a reason to continue using the original physical objects as well. A fourth question, independent of the third but closely related to it, is, “Will the presently surviving physical objects that transmitted texts in the past continue to be available?” Do they—that is to say—have a future in the most basic sense: will they survive? And if they do survive, can they be found in accessible locations?

All of these questions are obviously interconnected. An object cannot be used unless it exists; and though it may exist without being used, its chances of survival are greater if it is perceived to serve a function. As technology changes, the function of earlier objects is brought into question, because there is a convenience in having all materials in compatible forms, and because the newer forms are likely to be regarded, by a great many people, as superior to the older ones. But if no one sees any function for records from the past, and if, therefore, no one has any interest in them, then their survival is not a matter of concern in any case. Although the questions continually impinge on each other, taking them up separately can be an aid to clear thinking. The late twentieth century has seen a great deal of discussion of the whole subject, but much of the commentary has been vitiated by a failure to think through, in a methodical way, the complexity of issues necessarily involved. The following responses to the four questions posed here constitute an attempt to provide a logical framework for further discussion.

INTEREST IN PRIMARY RECORDS

Any concern for the future of primary records presupposes a future interest in them; and such an interest does not seem self-evident to everyone. A necessary foundation, then, for discussing this topic is an understanding of the inevitability—almost by definition, one might say—of an interest in primary records. It is essential, therefore, to know what definition of the term “primary record” leads to that conclusion; and the process of defining it reveals many of the issues that make the subject complex.

The word “record” is ambiguous in the same way that “book” is: sometimes it refers to a physical object, sometimes it denotes what is regarded as the content of a physical object, and sometimes its meaning shifts from one to the other within a single discussion, producing a confused argument. If a literary critic first employs “book” to mean “literary work” (as we all do when we speak of a “good book”) and then quotes from or discusses “the text of the book,” referring to the particular text physically present in the copy being read, the result is fundamentally flawed by its unexamined assumption that a verbal work is identical to any given text of it.^[1] The two are theoretically distinct, because a verbal work, made of language, is intangible and cannot reside in physical form. Each tangible object that carries a verbal text, such as a printed book, is one effort to transmit an intangible work, to make it transportable across time. But, each may be deficient, in one way or another, according to any of various possible standards for judging what ought to be there. The distinction between these senses of “work” and “book” is a necessary one, whatever terms one chooses to use. In coherent discussion, therefore, “book” must be used in only one way, and it seems sensible to employ the word to refer to a physical object, not to the intangible work that the object aims to transmit.

“Record” is simply a more encompassing term that includes “book” as one of its subcategories. Archivists are likely to think of “record” as denoting unprinted or unpublished material (especially when created as a by-product of the activities of an institution or individual).

But the extension of this archival term, and “archive,” to include printed artifacts has been common, as in phrases like “the print record” or “the national printed archive.” Archivists are no less guilty than literary critics of blurring the distinction between physical text and intangible work: they may think of a “record” initially in physical terms, but when they include microfilming as a procedure for “record management,” they have obviously switched to a concept of a “record” as a disembodied text. (The same switch applied to the word “materials” occurs in this sentence from a library newsletter: “Most brittle materials can be returned to usable condition by reformatting—transferring the information to another medium.”^[2]) If, to avoid this problem, we restrict “record,” like “book,” to the physical, it denotes a wider range of objects than books, from all kinds of handwritten and printed ephemera to business ledgers and card files. What links all of these objects is that they are the vehicles by which compositions in intangible media are transported. To make the compositions tangible, they are converted to notations that can be presented visually on physical surfaces—such notations as musical scores, choreographic diagrams, mathematical formulas, or alphabetical and numerical characters arranged to represent words and calculations.

A “record,” then, for present purposes, can be defined as an artifact carrying a text that represents in physical form an intangible work. (The word “document” can be used synonymously with it.) Such objects are aptly called “records,” because they do not contain the works themselves but only “records” of those works. There are other artifacts, of course, that convey works made up of physical media. They are not usually called “records,” because the works actually exist in them or are identical to them. Paintings, sculptures, and buildings, which use physical media, exist as physical objects. One might, for certain purposes, wish to think of them as “records” of human activity rather than as works of art, but in either case, one would be examining the same objects. Reproductions of paintings, sculptures, or buildings could also be thought of as “records”; but, as long as the works survive, the reproductions do not provide the sole means for approaching them, because the works can be apprehended directly. Tangible records of intangible works, on the other hand, are essential for reconstructing and experiencing those works, because there is nowhere else to turn (except, in some cases, to oral tradition, which poses analogous problems).^[3]

One might think, then, that the future of such records would be considered in the same terms as that of works in physical media, but by and large, it is not. Art historians and museum curators would scarcely condone the destruction of the artifacts they study, and their discussions of the future of those artifacts focus on preservation. But persons who deal with intangible works—from readers of literature to economic historians studying company archives—frequently believe that the content of what they are

concerned with can be separated from the physical objects in which it has appeared. To these persons, preservation is less likely to mean saving physical records than maintaining their “content” in some form. Discussions of records, as defined above, therefore, involve explaining the value of physical details in a way that would usually seem superfluous when talking about other kinds of artifacts.

This is where the concept of “primary” evidence comes in, though adding the word “primary” to “record” presents further complications. “Primary” means simply “first-hand”—that is, not derived or reported. Whether it also refers to physical evidence depends on the context. The term “primary record,” when used by those persons who equate records with intangible works, would not signify any physical details; it would mean a direct quotation from the figure being discussed or from an eyewitness account of an event, rather than a restatement made by someone farther removed from the subject of the discussion. From this point of view, an original manuscript and a microfilm of it would equally be primary records. If, however, one takes “record” to refer to an artifact, as we are doing here, then a “primary record” is a specific object containing a particular text of a work—the object being one directly connected with the historical moment that is the focus of one’s attention. Under this definition, if an author’s manuscript or a business ledger were considered a primary record, no copy of the texts in them—whether produced by handwriting, typewriting, photography, xerography, electronic scanning, or any other means—would be primary, because all such copies would constitute different physical objects.

One must remember, however, that an object regarded as primary for one purpose is not necessarily primary for another. Although an author’s manuscript (the manuscript itself, that is, not a photocopy of it) is a primary record for the study of the author’s method of working, it is not primary for an examination of the public influence of the work represented by the text in that manuscript. For that purpose, the primary record is made up of copies of the published edition. Similarly, to understand a particular critic’s response, one must have access to the edition, and preferably the specific copy of it, used by the critic. F.O. Matthiessen’s famous mistake in discussing Melville’s *White-Jacket* illustrates the point. He wrote about the phrase “soiled fish of the sea” rather than “coiled fish of the sea,”^[4] because he was using the Constable edition of 1922 rather than the original English and American editions of 1850.^[5] The Constable edition in its original 1922 printing—not in the 1963 Russell & Russell reprint, which did not exist when Matthiessen wrote—is therefore a primary record for the purpose of studying Matthiessen’s work, though it is not primary for understanding Melville’s intention. Because the latter is what Matthiessen was interested in, it is fair to say that his failure to look behind the Constable edition was a mistake.

If his purpose had instead been to investigate the reception of Melville's work in the 1920s, not only the Constable edition but also the other Melville editions available in the 1920s would have been primary records for him. But later reprintings or photocopies of those editions would not have offered primary evidence of what readers in the 1920s had in front of them, because all reproductions are new documents with their own distinctive characteristics. Although the features of any document are subject to alteration over the years, a document surviving from the moment one is concerned with nevertheless provides evidence unobtainable elsewhere for understanding that moment. Therefore, every textual artifact, however it may be classed in terms of "originals" or "reproductions," is potentially worthy of future study as a primary record. Even a private xerographic copy can be a primary record if a person who used it becomes a subject of historical inquiry—or, of course, if one's topic is the history of reproductions.

The definition of "primary record" adopted here is obviously not the only one possible. But, because the distinction between intangible works and physical texts is logically essential, limiting "record" to only one of them is conducive to rigorous discussion. If we agree to use "primary record" to mean *a physical object produced or used at the past moment that is the subject of one's inquiry*, we can further say that there must always be an interest in primary records, simply because no derived record can automatically be assumed to be trustworthy as a guide to what the original contains. Financial records, for example, will continue to be produced, in some form, as a by-product of a company's activity. Settling disputes over billing will require, in the future as in the past, recourse to those original documents, regardless of their form. In the same way, a questioned word or note in a verbal or musical text necessitates research into the most authoritative document available, because anything short of that (whether newly keyboarded or photographically reproduced) may be misleading, through human error or mechanical flaw. Obviously, primary documents may be untrustworthy as a record of what was intended, but they are the final authority for the texts that are actually present in them.

Of course, not everyone is, or needs to be, interested in historical accuracy. If one wishes to approach a text as a given arrangement of elements existing in the present, not as a link with a past time, one need not be concerned with distinguishing originals from reproductions (despite the fact that, paradoxically, the acceptance of the text of any document links one with the past moment when that document was produced). There is no need, however, to claim that everyone has or will have (or should have) an interest in primary records to make the point that such an interest must always exist, for some people will always have to turn to primary records, either because their temperament leads them to the study of the past or because their business requires them to locate the best evidence for a past

occurrence. There are other reasons, to be taken up below, for the importance of primary records. But the fact that they are "primary"—direct witnesses to the past and, thus, the ultimate sources against which the accuracy of any reproductions must be assessed—is enough reason for the permanent usefulness of all the records already produced and all those yet to be created.

FUTURE FORMS OF PRIMARY RECORDS

Speculations about the future, in any field, may be knowledgeable and shrewd, or ignorant and foolish, but they remain speculations nonetheless. Sometimes people engage in them through a desire to influence what happens and sometimes through disinterested intellectual curiosity. On the subject of records, the discussions in recent years have focused on an electronic future, with some discussions being eagerly receptive and others fearful or wary. Debates about whether printed books will, or should, continue to be produced have aroused strong feelings, on one side or the other, among large segments of the general public. This sort of controversy is natural enough at a time of significant change, and there is no doubt that the last part of the twentieth century and the early part of the twenty-first constitute such a time, with a proliferation of technological developments in the electronic manipulation and storage of texts. But these debates really have no relevance to the present topic.

Primary records, as defined here, will continue to be produced in some form and will continue to be important, regardless of their form. A concern with the future of primary records is not tied to any particular form but to whatever forms primary records take—the forms they have taken in the past and the forms they will take in the future. They have always taken multiple forms, and presumably they always will take a multiplicity of forms, though the dominant forms shift over time. Electronic forms are at the beginning of their ascendancy now, just as letterpress forms were (at least for some purposes) five centuries ago. Some people seem to believe that anyone arguing for the preservation of physical records from the past must be opposed to computers; and while of course some arguments may be motivated by a fear of change, the serious arguments for the retention of primary records imply no attitude, one way or the other, about the relative desirability of electronic forms. The electronic handling of texts offers so many advantages that it is hard to see why anyone would not welcome it. Be that as it may, one's welcoming it or not welcoming it has nothing to do with recognizing the importance of all primary records and understanding that the preservation of individual surviving electronic forms of texts will be just as imperative in the future as the preservation of handwritten and printed forms is at present.

Not only is the future form of new texts a matter of current discussion, so is the question of whether old texts should be repackaged in new forms. An awareness of the significance of primary records is not incompatible with a desire to see old texts converted to forms that make them amenable to the advantages of electronic access and searching. What it means, however, is a recognition that any converted form can never stand as a full substitute for the original record from which it derives. There is no reason not to use such a secondary record for convenience, so long as one understands its limitations as a source of documentary evidence; but to think, as some people do, that a converted form can replace the original is to disregard the role of primary evidence in pursuing the past. This issue is not new, for it has existed as long as people have been copying visible texts from one surface to another; but the electronic revolution is so pervasive at present that it sometimes seems to have produced the issue.

A useful illustration is the current conversion of many library card catalogs to electronic form, followed by the disposal of the cards. Some of the questions raised by these activities were brought to a large audience by the novelist Nicholson Baker's long, well-written, forceful article in *The New Yorker* of 4 April 1994.^[6] Baker's defense of the card catalog was occasionally sentimental, but it enumerated some legitimate reasons for dissatisfaction with the conversions that have been taking place, notably the errors that result in even the best conversions and the fact that budgeting constraints have caused some library administrators, even in major research libraries, to ask for something less than the most sophisticated conversions available. It is hard to imagine, however, that these questions would have been the focus of a major article in a mass-circulation magazine if the computer had not been involved—if, that is, the problem had not been symbolic of the computer's many intrusions into familiar ways of doing things. (That the article touched a nerve is shown by the amount of discussion it engendered (e.g., see Barker,^[7] Carpenter,^[8] Douglas,^[9] and Max^[10].) Yet, the real subject was not computerization but rather the relation of primary and secondary records. Although Baker chose not to say so, computerization was only the immediate occasion for taking up an old issue—old even in relation to library catalogs.

Retrospective conversions of card catalogs were, after all, undertaken in precomputer days as well. The National Union Catalog, for example, was once a card catalog in the Library of Congress, made up of copies of cards contributed by libraries throughout the United States and Canada. The process of turning it photographically into a book-form catalog, published as *National Union Catalog: Pre-1956 Imprints* between 1968 and 1981, involved hundreds of thousands of editorial judgments, such as deciding which cards could be eliminated (as duplicative) and replaced by library symbols added to other cards.^[11,12]

Inevitably, errors were made, but there is now no way to check entries in the published catalog against the cards. One may not normally think of a union card catalog as a primary record, because the cards are not the books themselves, and even the cards are derived from the cards in other catalogs. But as a reference tool, as a particular grouping of references, the cards once housed in the Library of Congress were a primary record, for they constituted the original form of this tool. Any edited version of it is a derivative form, which despite its advantages still rests on the original for its authority. No computers were involved, but this conversion raised the same questions that Baker's article implicitly (if not explicitly) raised.

Another large card catalog, that of the New York Public Library, and the card catalogs of many special collections or specialized libraries have been similarly converted by photography into book-form catalogs. In these instances, the original catalogs have not uniformly been discarded, but the common tendency to think of the published catalogs as fully adequate replacements ignores the potentiality for defects in any reproduction. Publishing card catalogs in book form serves to reinforce the fact that the texts of such catalogs constitute reference works and that their reproduction, by whatever means, is analogous to the reproduction of other reference books, or other books of any kind. The conversion of card catalogs (whether by photography or by rekeyboarding) deserves no more, and no less, publicity than all other conversions of recorded texts. There is no reason to object to the conversions, if they are responsibly carried out at the highest level that current technology can offer. Indeed, it would be foolish not to take advantage of the benefits of new technology. But one can legitimately complain if the converted or reproduced form is thought to supplant the original and if the original is therefore not retained. (The fact that many libraries have an "official" and a shelf-list card catalog as well as a public one does not affect this point, for each of those catalogs is a separate record, and whichever one is used as the basis for a reproduction is the primary record for that purpose.) The future forms of primary records will be whatever they turn out to be; but, even though we may find an interim usefulness in converting many old texts to the new forms, those forms have no bearing on primary records of the past, the forms of which are historical facts.

USES OF PRIMARY RECORDS FROM THE PAST

There are many reasons for the retention of primary records as defined here, despite the usefulness that derived forms undeniably have for some purposes. It would not matter, however, whether there were any reasons other than the one already given: that primary records—the original physical objects—constitute the authority for judging every kind of copy. Occasions for questioning

reproductions (in whatever form) occur continually. If the primary records from which the reproductions derive do not exist, those questions can only be speculated about, and any conclusions then drawn from the reproductions do not rest on as firm a foundation as if they had been based on the original artifacts. Whenever one settles for something other than the original (or has no choice but to do so), one is deprived, quite simply, of the best evidence.^[13]

There are other reasons to use the originals, for they always contain unreproducible evidence. Every means of reproduction has its own characteristics, its own advantages and disadvantages; but whatever they are, they always leave some details unaccounted for and add new characteristics of their own. Electronic texts that have been freshly keyboarded, for example, have the advantage of being easily searchable for any given word or phrase; but they do not allow one—as photographed texts do—to see the typography (or handwriting) and lineation of the original. For this reason, electronic renderings of texts from the past, if they are to serve their readers well, should always be made up of a combination of keyboarded texts and scanned (“bitmap”) images. But, even if texts reproduced in these ways were accurate as far as they can be (such accuracy to be determined, of course, by reference to the originals), there would still be important evidence that remains inaccessible, because reproductions do not give readers access, for instance, to the original paper, ink, and binding. “Accuracy” is clearly a relative matter, dependent on the details one is focusing on in a given instance. The common misconception that verbal texts can easily be extracted from their physical embodiments leads frequently to calling a reproduction “accurate” if the words and marks of punctuation are accurate. In addition, when the original typography or handwriting is reproduced, many people do not understand how the original is being misrepresented. Yet the fact that physical texts are our primary way of getting at intangible works means that the shape, feel, and structure of the objects conveying those texts—all the characteristics of the objects, in other words—constitute relevant evidence for assessing the texts and reconstructing the works (or, put more simply, for reading).

The physical evidence in books (or any other artifacts, for that matter) can be studied for two kinds of information: the light it sheds on how the objects were conceived and produced, and the insight it offers on how the objects have been responded to and treated since the time they left their producers’ hands. Those who concentrate on the first of these in respect to printed books are often called analytical bibliographers.^[14,15] Although the field of analytical bibliography was developed in connection with the study of fifteenth-, sixteenth-, and seventeenth-century books, especially the textual investigation of the plays of Shakespeare and his contemporaries, this kind of work has by now uncovered significant details about the manufacture of books of all periods. It has been particularly

associated with literary study, for analytical bibliographers have repeatedly demonstrated the way in which a detailed knowledge of the production history of a book is crucial for establishing the evolution and authority of the text printed in it.^[16–20]

The amount of such analysis that can be undertaken with rekeyboardings or reproductions is extremely limited. One might at first think, for example, that the analysis of variant spelling and punctuation, which is useful in the attempt to distinguish portions of a text set by different typesetters, could be pursued with rekeyboarded texts (assuming their accuracy). But knowledge of the lineation of the original is essential for this purpose, because the spacing within a line and the position of the spelling or punctuation at issue are relevant to the interpretation of a typesetter’s behavior. Photographic, xerographic, or electronic images of the originals are therefore necessary; but they, in turn, are insufficient for other kinds of typographical analysis. The identification of broken types, for instance, is a standard technique for working out the order in which pages were set and printed.^[21] But such identification requires that one distinguish (often with the help of magnification) the traces of the typeface impression within the total ink smear, which can be affected by many factors; and reproductions never preserve this evidence. As Adrian Weiss, who has studied this matter intensively, said, “the nature of the typographical evidence present in reproductions renders them highly untrustworthy for absolute identifications, even in regard to those damaged types which seem obvious in a reproduction.”^[22]

If the failure of reproductions in this respect is surprising to some people, no one is startled by the fact that reproductions are useless for the analysis of paper, or of the way the type bites into the paper, or of the structure of the folded sheets in a book. Yet, such analysis reveals information important for printing history, literary history, and textual study. Identification of paper (through the study of its watermarks and chainlines or, if those features are lacking, as they are in many papers of the last two centuries, its texture, weight, and color) can be of assistance in dating a book, as in the celebrated instance of the *Missale speciale*.^[23] It also helps one to detect cancel leaves or, more likely in later books, whole cancel gatherings (that is, leaves or gatherings inserted to replace others that had been removed). The indentations made in paper by the bite of the type can reveal the order in which the two sides of a sheet were printed, because the one printed second will be smoother.^[21,24] And, the way in which the sheets were folded and sewn together can be established only by examining the paper and sewing, for the printed signatures that mark the early leaves of gatherings (in most books before 1900 and many afterward)—and that can thus be expected to show up in reproductions—cannot be relied on for this purpose. Signatures may accurately indicate the number of leaves in gatherings (as they usually do in the hand-press period), but they do not show

whether the gatherings consist of folded single sheets, multiple sheets, or half sheets. It is not uncommon in nineteenth-century books for signatures to be unrelated to the actual gatherings.^[25,26] These pieces of information, and others like them, retrievable through bibliographical analysis, are obviously relevant to printing history and, through their contribution to the story of how particular texts were made publicly available, to literary history. Their broader relevance to the concerns of readers comes through their role in textual criticism and scholarly editing. Knowing how a text was handled by the persons who printed and published it helps one to assess the relative responsibility of author, publisher's editor, typesetter, proofreader, and so on, for specific words or features of the text.

Furthermore, reproductions normally represent single copies; but there is no limit to the number of copies that are useful for textual collation and physical analysis. Differences among copies of the same editions exist in books of all periods, as a result of stop-press alterations, damage to type or plates during printing, changes or handling between printings, duplicate settings, cancellations and replacements of leaves or gatherings, and—in the era of edition binding—variations in the design and wording on bindings. Thus, no matter how many copies one has looked at, there is always the possibility that the examination of additional copies will disclose further variants. Although Charlton Hinman inspected in detail about two-thirds of the Folger Library's 80 copies of the Shakespeare First Folio,^[17] new variants are still being found in other copies.^[27] David L. Vander Meulen has learned new facts about the text of Pope's *Dunciad* in an ongoing investigation that by 1988 had encompassed some 800 copies of the early editions.^[28] No period or kind of publication is exempt: there are significant differences, for example, among the so-called "editions" of nineteenth- and twentieth-century newspapers. And, the bibliographers of the famous Tauchnitz series of paperbacks (1841–1955), after examining a total of 56,000 copies and discovering thousands of previously undetected impressions and issues, can still say that, as additional copies are looked at, one in 60 is likely to be an unrecorded impression and one in 20 an unrecorded issue.^[29] The ease with which electronic texts can be altered (both intentionally and inadvertently) is already a matter of concern to some readers seeking the primary records of writings that were originally transmitted in digital form. It is misleading, however, to contrast this instability with what one writer on the subject calls "the fixity of text in the print world,"^[30] for variations exist in printed editions of all periods. There is no means of textual transmission that is exempt from the possibility of alteration, and printing technologies have been a sophisticated step in the progressive development of easier ways to produce textual changes.

All of these uses of physical evidence for learning about the production history of printed books seem

obvious enough, once they are pointed out, but most readers are not likely to be familiar with them. These approaches have been primarily employed by textual scholars, after all, and their impact on readers occurs through the effect they ultimately have on the texts of new editions. In contrast, the other large category of information dependent on physical evidence, the postproduction history of books, requires less explanation, for all readers are aware, from personal experience, that the reading of books is affected by their design, by the contexts into which verbal texts are placed. Although typographical arrangement can be seen in reproductions, its scale and placement on the page are not always evident, and the quality of the paper, the relation of ink and paper color, and the characteristics of the binding, endpapers, and jacket are of course not accessible in reproductions. Some authors have taken considerable pains with such matters, as Congreve did when preparing the three-volume octavo edition of his *Works* in 1710.^[31] Whether the author or the publisher was responsible for format and layout, and whether or not one wishes to regard those features as part of the verbal work, they were often deliberately chosen to produce certain responses in readers, and they always produce responses, even if not necessarily the intended ones. The totality of a book's design constitutes a cultural message and is part of what the book offers for reading. D.F. McKenzie effectively demonstrated this point at the beginning of his centenary lecture to the Bibliographical Society, when he explored the meanings conveyed by the paper, format, and bulk of a blank book:^[32] "every book," he observed, "tells a story quite apart from that recounted by its text." Historians are now charting, more intently than ever before, the role of book design in various times and places. The history of reading has become one of the most studied aspects of the history of books.^[20] Scholars are not the only people who need access to artifactual evidence. Because the look and feel of books affect reading, all who wish to experience texts with as much historical understanding as possible require the objects that survive from particular past times.

These points are clearly valid for all varieties of printed matter, not just those with texts that can be classified as belles lettres; and they are applicable as well to all manuscript material. Scrutiny of the inks and papers in a manuscript is essential for drawing inferences about its production history—for working out stages of revision, for example, or simply determining which ink marks show through from the other side of the paper. And, whether the text consists of prose or of the entries in a business account, its physical setting plays just as important a role in understanding it as physical evidence does in the case of printed matter. The experience of reading an electronic text is also inevitably affected by its physical presentation.^[33,34] The information conveyed by the physical object as a whole is what Ruth Perry called "embodied knowledge." In her eloquent statement at the Houghton

Library 50th anniversary symposium,^[35] she said, “the object itself is part of the material culture of its own time, and carries with it something of the social context that produced it.” For those interested in the past, there will always be uses for primary records, because their “content,” their “meaning,” can never be fully transferred to any other objects.

SURVIVAL AND ACCESSIBILITY OF PRIMARY RECORDS

Whether the primary records that now exist will survive and be available to serve these purposes in the future depends in part on the materials out of which they are made, in part on the unalterable vicissitudes they encounter, and in part (the largest part, in fact) on the attitudes people hold about them. Some of the destructive events that befall artifacts, whether caused by natural forces or human actions, are of course unpredictable or, in practical terms, unavoidable, but not all are inevitable, for human attitudes can often prevent them or alleviate their effects. Pre-nineteenth-century items are likely to be relatively safe, because the paper used in them is high in rag content and because they are widely perceived to be valuable in monetary terms. The voluminous stock of nineteenth- and twentieth-century materials, on the other hand, is certainly at risk, because many contain highly acidic wood-pulp paper that becomes brittle and because the vast majority are regarded as having insignificant market value. When these facts are combined with a belief that verbal content and physical form are distinct, the items considered important enough to be microfilmed or otherwise (as in electronic form) reproduced are in danger of being discarded afterward. And what is considered important or unimportant at one moment, it should be added, may not be so regarded at another.^[36–38]

Considerable attention has fortunately been paid to the problem of books with brittle paper, and the pages of a great many books have been microfilmed as part of individual library programs or of the massive cooperative effort overseen by the Commission on Preservation and Access. As a general rule, there has been no concern with what happens to the artifacts after microfilming. In practice, most libraries have not kept them, regardless of the state of their deterioration or their mutilation by the microfilming process, and they have regularly been destroyed. Sometimes the point is made that items of “artifactual value” will be kept, as if it were logically possible for artifactual value (the value inherent in an artifact) not to be present in some artifacts.^[39] Although no known treatment can return brittle paper to its original condition, there are deacidification processes (likely to become less expensive in the future) that can retard or stop the deterioration,^[40] and whatever can be salvaged will be useful to future readers. Commonly, however, the

existence of a microfilm or electronic copy of the text in a deteriorating book causes many people to believe that the artifact from which the copy was made is disposable. Although some pieces may be doomed to eventual destruction in any case, this notion serves to hasten their disappearance.

The question of the stability of the objects carrying texts has most frequently been discussed in relation to books containing acidic paper, but one must remember that other vehicles for textual transmission have limited life spans as well. As the *Scientific American* noted,^[41] electronic documents are “far more fragile than paper.” “The contents of most digital media,” as stated in the article, “evaporate long before words written on high-quality paper.” The text on a magnetic disk, for instance, can be completely erased by oxidation or stray magnetic fields. As more and more writings are initially produced in electronic form, the future problem of preserving primary records will be even more acute than the present one. (This problem is in addition to the difficulty of access resulting from the obsolescence of software and hardware).

Of course, the urge to make reproductions is not limited to instances in which physical deterioration of originals has been recognized. Texts of all periods are often reproduced, to save wear on the originals and to make the texts more accessible, even if the objects carrying them are not in danger of disintegrating or becoming otherwise unusable. When the reproductions take up less space than the originals, librarians sometimes prefer the reproductions and deaccession the originals. This practice may well increase, as the inventory of texts available in electronic form becomes ever larger. Certainly some library administrators have already predicted that book stack space can be diminished in the future. Although the books thus removed from stacks are not necessarily destroyed, they may wind up in less accessible locations. The accessibility of artifacts, not simply their survival, is of vital importance for the study of the past. When one understands the inseparability of texts and their transmitters, one sees that the phrase “preservation and access,” often stated as the dual aim of textual reproduction, applies equally as the goal of a concern for textual artifacts. The uses of physical evidence, described above, imply, as far as printed books are concerned, the significance of multiple copies. A multiplicity of copies makes possible, even likely, a widespread distribution of copies. Whether one is looking at physical details as evidence of printing and textual history (in which case, every copy is a potential source of new information) or as an indication of a book’s cultural milieu, access to copies is essential for the fullest kind of reading, where a physical text and its physical setting are read together. If the existence of electronic reproductions of old texts causes books to be moved from community and academic library stacks to less accessible (and perhaps noninstitutional) locations, the opportunities for this kind

of reading are lessened. The idea that reproduced texts are replacements for the originals can thus affect not only the survival of artifacts but also the availability of those that survive.

Some of these points are well illustrated by recent events at the Kansas City Public Library, where the decision was made to dispose of the Rare Book Collection. This is not the place to debate whether the action was appropriate but only to note the reasoning that was considered adequate to justify it. The director of the library said that “it is the preservation of the ideas and information contained in the book, rather than the book itself, which the library preserves and makes available to the community.”^[42] This statement shows no awareness of the connections between text and artifact, or of the consequent usefulness of physical evidence to all readers, whether scholars or not. Indeed, the notion that so-called “rare books” are assembled only for scholars provides another of the arguments given for the deaccessioning: the director states that the “role of the public library is educational but not academic” and that its function is not the support of scholarly research. It is no doubt the case that most readers have not thought about the importance of artifacts in the reading process, but one can argue that a community library might appropriately undertake to educate them in this regard. Public libraries play an important role in bringing historical embodiments of texts, and the sense of the past they impart, to a wide readership. Still another argument for the decision is that the library has no climate-controlled storage space, as if “rare books” and books in the general stacks were somehow different in kind (if not in their physical makeup) and that the necessity for properly housing “rare books” does not extend to other books (any of which may be considered “rare” from a different viewpoint). If the flexibility of the line between “rare” and “nonrare” had been recognized, the additional argument that the Kansas City rare book collection had no focus might well have seemed irrelevant, because its “focus” would not then have been judged separately from that of the whole collection of the library. (It can be argued, as I have, that a library’s entire book stack should be regarded as a “special collection” and treated as such.^[35,43]) The director of the Kansas City Public Library should not be singled out here for special comment: his remarks could have been made by many other librarians. But for that reason, the remarks usefully point out a common misconception.

Its ubiquity is revealed by its presence in a great deal of the writing and speaking on the future of libraries. There has been no shortage of conferences, reports, and special issues of periodicals exploring the impact of digital technology on humanistic scholarship. In all of this commentary, there is scarcely any recognition of the role of artifactual evidence in reading, while many statements imply the replaceability of originals. For example, at the April 1990 meeting of the American Council of Learned

Societies, which addressed the topic “Scholars and Research Libraries in the 21st Century,” considerable emphasis was given to the idea that “access” will replace “ownership” as a goal of libraries—electronic access to texts, that is, in contrast to ownership of the objects that originally transmitted them. One speaker,^[44] welcoming the new ways to “repackage” verbal works, saw the old system in terms of inefficient duplication (“multimillion volume collections. . . housed in massive buildings duplicated across the country at enormous expense”), overlooking the importance of multiple collections of artifacts for providing widespread access to physical evidence and to the historical insights that such evidence allows.

Two and a half years later, the Mellon Foundation’s report, *University Libraries and Scholarly Communication*,^[45] also made much of the opposition between ownership and access. It stated, in its third paragraph, that we have lived “with a world in which the technology of publication meant that access *required* ownership,” but new technologies, it was stated, “allow the possibility of uncoupling ownership from access, the material object from its intellectual content.” These comments led the authors to the question, “What is the viability of the traditional model of the library as a single-site comprehensive collection of printed materials?” Neither this question nor the more detailed discussion later in the report adequately recognizes that the concept of primary evidence is an essential ingredient of any useful response to the question. Indeed, the idea of “uncoupling. . . the material object from its intellectual content” logically involves rejection of the distinction between primary and derived documents. Even when the report turns to a future in which “the primary artifact is itself electronic,” it does not pursue the implications introduced by the word “primary.” It alludes, for instance, to changes that such artifacts will produce “in the relationship between interpretive works and the underlying data or primary texts on which they are based,” as if that relationship could ever be different, regardless of the original form of the “primary texts.”

The point is also made that “print products” will still have an “important role” to play in a world of electronic publishing. No note is taken of the fact that such products, when they are printouts of electronic texts, will be derived documents. What is ultimately missing from the discussion is an awareness of the immutable gap between intangible works and the tangible means of their transmission. The phrase “dematerialization of information” is used as a description of what the new technology is achieving. Actually, it describes what the process of reading has always accomplished, as readers extract works, or “information,” from the physical details before them. Electronic documents offer a new set of physical details, but physical, nevertheless, and readers will still be in the position they have always been in. What is most basic for them, if they are historically minded, is not what the physical form

happens to be but whether a given document is primary or derived.

The same misconceptions reappear continually in other reports. In the summary of the proceedings of the 1992 Irvine conference on “Technology, Scholarship, and the Humanities,”^[46] for example, there are repeated references to an envisioned “national electronic library” or “digital library” of millions of volumes as a national priority, without any suggestion that having those volumes in this form (though unquestionably helpful) would not eliminate the need for reading them in their original forms. Indeed, the frequent linking of this project with “preservation” might seem to imply the opposite. The published report of the 1993 Bellagio conference on “Preserving the Intellectual Heritage,” sponsored by the Commission on Preservation and Access,^[47] also failed to address the question of primary evidence, even suggesting that the reason for scholars’ resistance to microfilm is the “incredible force of custom and tradition.” This report briefly noted that “some scholars make strong arguments for the conservation of the actual publication, the object itself.” In response, it only suggests conserving samples or the “one best remaining copy” of “particularly important” works—an idea that shows no awareness of the nature of bibliographical evidence or of the need for broad access to it. (In the formal resolution that emerged from the conference, access to reproductions is not distinguished from access to originals for instance, the phrase “to promote more effective means of storage, conservation and preservation, to insure access in the future,” in a context in which “preservation” refers to transferring texts to new physical objects).

Similarly, the Spring 1993 number of *Representations*, devoted to the subject “Future Libraries,”^[48] contained no discussion of the future use of old books as primary evidence. Even Geoffrey Nunberg’s thoughtful article on “The Places of Books in the Age of Electronic Reproduction” ignored this topic, though it includes a good description of the role of physical details in reading and briefly recognizes the distinction between texts that originally appeared in printed form and those that were initially disseminated in electronic form. Roger Chartier’s contribution, “Libraries without Walls,” asserted that, in the electronic age, “texts are no longer prisoners of their original physical material existence.” But there was no indication of why such liberated texts are inappropriate for many purposes, despite Chartier’s clear understanding, expressed in the next paragraph (and in many of his other distinguished writings), that a text “is no longer truly the same” when it is moved from codex to monitor screen, because the new “mechanisms” of transmission “modify the conditions of its reception and its comprehension.” In the 1994 Cornell symposium on “Digital Imaging Technology for Preservation,” sponsored by the Research Libraries Group, M. Stuart Lynn neglected artifactual evidence in his vision of the future in which “we convert back

and forth between the use of digital technologies for storage and transmission and analog technologies for human presentation and interaction.”^[49] What he called “paper facsimiles,” produced from digital images of printed pages, can be, in his view, “reshelved for traditional forms of access,” though the essence of the traditional process is not using paper but locating primary evidence.

Whatever else these various publications, and others like them, have accomplished (they contain much thoughtful comment), they do not build their arguments on a firm understanding (or at least an explicit acknowledgment) of the way historical study employs artifacts. Unfortunately, the level of sophistication in thinking about the physical book is frequently no higher among participants in conferences on the electronic future (many of whom think of themselves as “information specialists”) than it is among the general public, or advertisers. The publisher Chadwyck-Healey’s advertising brochure for its CD-ROM entitled *The English Poetry Full-Text Database* (1994) stated that “the texts are more accessible than any printed source and yet take up no shelf-space. There are no problems of conservation and security of rare volumes and no significant cataloging costs.” There is obviously a built-in contradiction here. Why should “rare volumes” require “conservation and security” if the texts that are now made “more accessible” are the equals of the texts in those volumes? Despite the illogic of the statement, it will be persuasive to many people and thus reflects the popular perception of the situation.

One cannot entirely blame the public for this view, however, when the statements of prominent library administrators are similarly deficient. On 13 October 1994, the Librarian of Congress, James H. Billington, held a press conference to announce three donations, totaling \$13 million, for the first phase of the creation of a National Digital Library. In his remarks, he spoke of making, through this project, a “mother lode” of “original” materials “accessible to people across America.” He also predicted that the “user-friendly book will not disappear.” By neglecting to say anything about the differences between originals and reproductions and by implying that the choice among presentations of texts is only a matter of personal preference, he was missing a significant opportunity for educating the public in the concept of primary evidence.^[50,51] An earlier occasion on which Library of Congress officials spoke on this topic was the 10 March 1989 meeting of the Library’s Council of Scholars. Although at that gathering Stephen R. Ostrow argued for a “collection-based institution” and made the distinction between primary and derivative documents, he was paired on the program with Robert Zich, who saw the interest in books as simply the “worship of original formats,” which he designated as “idolatry” and “fanaticism.”^[52]

Zich is not alone in his view. For example, Michael Lesk took essentially the same position in his 1997 book *Practical Digital Libraries*.^[53] As an administrator of the

Digital Library Initiative, he believed that libraries should, in general, replace books made of printed paper with electronic versions of the texts in them. The motivation for reproducing large quantities of texts is no longer simply to salvage them from objects thought to be disintegrating. Now, as Lesk and others see it, even the texts of books that are not deteriorating should be converted, because their electronic forms are searchable and take up (if on CD-ROMs) only a fraction of the space occupied by bound volumes or (if on the Internet) no space at all. This thinking lies behind several large projects, such as the Mellon Foundation's JSTOR, an Internet database of scholarly journals.^[54] The searchable database that underlies the images unquestionably makes access to journal articles easier. But the idea that it also saves space (accepted by many of the subscribing libraries) ignores the fact that it cannot possibly render the originals unnecessary.

Just as Stanley Katz could observe at the 1992 Irvine conference^[46] that adequate funding for the humanities and the arts will not come until "the public understands that it is in its interest to invest much more heavily" in them, so one can say that effective support for the retention of textual artifacts, and not just the texts, depends on a broad-based awareness of the fundamental role that such artifacts play in reading. The number of voices thus far raised to make this point is small compared to those championing reproductions. There is no reason, of course, for these two opinions to be thought of as opposed, or for those expressing them to think that both cannot be simultaneously embraced. An appreciation of the benefits conferred by reproductions—enormous benefits in the case of electronic texts—is not incompatible with an understanding of their limitations and of the irreplaceability of the originals.

Those who have spoken in defense of artifacts have usually expressed this comprehensive view. For some examples, one could turn to the published remarks of several speakers (Barker, Gundersheimer, McKitterick, Mason, Perry, and Tanselle) at the September 1992 Houghton Library symposium, a rare instance of a conference that repeatedly recognized the value of artifactual evidence.^[35] (An earlier Harvard Library publication that recognized the importance of originals was the special issue of the *Harvard Library Bulletin* on "Preserving Harvard's Retrospective Collections."^[55]) Another public occasion that included a particularly trenchant statement of the same kind was the October 1993 annual meeting of the Association for Documentary Editing, where Elizabeth Hall Witherell devoted her presidential address to this topic.^[56] "I see," she said, "that the raw material that I need and that future editors and historians will need is in jeopardy"; the "threat is that, having been microfilmed, or digitized, or microfilmed and then digitized, the originals will be discarded with some relief by those making very hard decisions about allocating money and space."

Her main point is concisely and effectively phrased: "We cannot rely exclusively on copies, though we may begin our work with them, because they do not tell the whole story that we need to know."

One of the most powerfully expressed statements on the place of artifacts in reading was offered by D.F. McKenzie at the conclusion of a conference on "Scholarship and Technology in the Humanities" at Elvetham Hall, Hampshire, in May 1990.^[57] Because books "encode the history of their production," he said, "It follows that to abstract a conceptual or verbal information content from them by representing them in another medium is to contradict the very assumption that the artefact is the product of a distinctive complex of materials, labour and mentality." To reproduce texts is "an impoverishment, a theft of evidence, a denial of more exact and immediate visual and tactile ways of knowing, a destruction of their quiddity as collaborative products under the varying historical conditions of their successive realizations." It is ironic, but not unexpected (given the usual approach to such matters), that the official "Resolutions" adopted by the conference (and printed only 10 pages after these sentences of McKenzie's) include the following: "Encouragement should be given to the conversion of printed texts to machine-readable formats and to the improved electronic transmission of such texts." (The only reference to conservation in the "Resolutions" failed to distinguish the use of originals from the use of reproductions: "In view of the rapid deterioration of printed materials, there should be national and international efforts towards their conservation and their reproduction in alternative forms.")

In recent years, there has been a growing interest in the artifactual evidence in printed books on the part of literary and cultural historians and those in the flourishing field of *histoire du livre*.^[20] This interest has been reflected in the activities of the Modern Language Association of America (MLA). In June 1992, the executive director of that association, Phyllis Franklin, speaking at the American Library Association convention, reported on a survey she had taken of the views of scholars in the humanities.^[58] Although, she said, they "respect the access photocopies and microfilms of the written and print records allow" and "welcome electronic databases of all kinds," looking forward to "the creation of electronic texts of publications that appeared originally in print," the majority also "argue that our society should maintain as complete a record of print as possible because such a record will continue to be essential to scholars who wish to study the print era." They felt that "saving a few copies of a book" is not sufficient. The following February, the MLA Council established an Ad Hoc Committee on the Future of the Print Record, consisting of eight scholars and librarians (Shelley Fisher Fishkin, Everette E. Larson, Philip Lewis, J. Hillis Miller, Ruth Perry, Alice Schreyer, Philip Stewart, and G. Thomas Tanselle, chair). Despite its name, the committee's purview was understood as textual artifacts

of all kinds, not just printed ones. Its charge was to prepare an official MLA statement on the subject, to assist in disseminating it, and to engage in any related activities that would help to create public awareness of the issues. At the MLA's December 1994 convention in San Diego, the committee held three sessions, where, in addition to general discussion, 16 scholars and teachers reported instances in which primary records were crucial to their work.^[59] The committee's statement explained the importance of retaining artifacts after the texts in them have been reproduced and also urged the establishment of standards for the creation and identification of reproductions.^[60] Unfortunately, the effect of this statement was somewhat blunted by the appearance, four years later, of another MLA-endorsed statement, *Preserving Research Collections* by Jutta Reed-Scott,^[61] which takes a step backward. It focuses on access through reproduction and does not recognize the value of physical details, except for items "that have scholarly value as artifacts," apparently unaware of the logical absurdity of that often-used phrase.

Another organization that was preparing a draft statement at the same time as the MLA is the American Institute for Conservation of Historic and Artistic Works (AIC). Its Library Collections Conservation Discussion Group (chaired by Maria Grandinette and Randy Silverman) wished to make more widely known the research value of publishers' bindings and the consequent importance of preserving them, using simple protective procedures or nondamaging conservation techniques.^[62] (A survey of attitudes toward rebinding books, including those from the period before publishers' bindings, was offered in the spring of 1995 by Michèle Valerie Cloonan. She noted, "The current approach to conservation is to save as much of the original as possible in a rebind."^[63]) Support for the preservation of artifacts has also come from a surprising source, BookLab, Inc., a firm that produces paper replacement copies of deteriorated books. In a series of pamphlets, this firm has promoted the idea that the originals should be regarded as "leaf masters" and retained as the sources for future reproductions.^[64,65] Although the importance of access to physical evidence in reading is not sufficiently appreciated here, there is, nevertheless, a recognition that reproductions can be misleading and impermanent and that "a continuing role for originals"^[64] exists, along with a corresponding need for facilities in which to house them. This concern with housing reminds one of a somewhat similar proposal, from the world of scholarly bibliography, for depositories in which books can be placed after microfilming or digitization.^[66] The motivation of bibliographers is not the same as BookLab's, but both approaches share a disapproval of the widespread practice of discarding originals after reproduction.

Still another encouraging sign was the establishment in June 2000 of a Center for the Cultural Record at the Graduate School of Library and Information Science at

the University of Texas at Austin. Its aim is to bring together, for mutual reinforcement, instruction in the fields of archives and records management, preservation and conservation, and museum studies. In the words of one of its initial statements, the center reflects a "growing convergence of interests" among these fields, which have "common foci" in that they are concerned with "managing the source original in a digital environment."^[67] The act of treating verbal documents and museum objects under the same rubric is significant for its recognition of the essential role of artifacts in all approaches to the human cultural heritage, and one hopes that this action and its implications will be widely noticed.

Thus there have been some events to be applauded, but the primary credit for acquainting a broad public with the importance, and endangered position, of verbal artifacts belongs to Nicholson Baker. Following his card catalog article, he wrote, for *The New Yorker*, an exposé of the extensive book-discarding activity of the San Francisco Public Library, about which he had already raised public concern in San Francisco.^[68] Then, in the summer of 2000, he published in *The New Yorker* an eloquent essay about the British Library's decision to dispose of a large part of its great collection of non-British newspapers.^[69] Because most of the large American collections of American newspapers had already been decimated (on the grounds that space is scarce and that microfilms are an adequate substitute), many of the British Library runs of major American papers were the best surviving ones (and in some cases, probably unique). Baker's thoroughly informed piece made clear the tragedy of the British Library's action. And Baker announced that, in order to save at least some of the papers, he was using his own savings and raising additional money to establish a non-profit American Newspaper Repository. His essay aroused a great deal of attention,^[70,71] both favorable—such as H. R. Woudhuysen's article in the *London Times Literary Supplement*^[72]—and unfavorable—such as an attempted defense of the British Library's action by its chief executive, Lynne Brindley.^[73] Baker had already been working on a book dealing more broadly with the movement by libraries to replace printed matter on paper with space-saving reproductions. In the spring of 2001, he published *Double Fold: Libraries and the Assault on Paper*,^[74] a remarkably researched account of the history and unfortunate consequences of library administrators' many schemes based on the misconception that reproduced texts are the equivalent of the originals. It is to be hoped that Baker's powerful and widely reviewed book will inaugurate a new period in the understanding of the nature of verbal artifacts.

Baker has, of course, focused on paper artifacts. Another task for the future is to confront the problems of identifying and preserving the originals of records that were first produced in electronic form. Fortunately, some people have made a start in thinking about this question.

There have, for example, been projects dealing with the subject at the University of Pittsburgh^[75] and the University of British Columbia,^[76] and the Council of Library and Information Resources established a Task Force on Archiving of Digital Information, which published a report in 1996^[77] and held a conference on "Authenticity in a Digital Environment" on 24 January 2000.^[78] Several of the speakers at this conference thoughtfully grappled, in a preliminary way, with the thorny issues of how to define a primary digital record and what role design features play in such documents. One tendency that must be recognized and counteracted, however, is to conflate the disparate concepts of authenticity, textual accuracy, and correctness of content. The mere fact that a text has been copied "accurately" (in terms of words and punctuation) from an original source does not make the new document (the text in a setting) authentic. Furthermore it does not signify that the wording and punctuation, and therefore the meaning, are what the author intended, to say nothing of being factually accurate. Clear thinking about digital texts, as about those on paper, demands vigilance in maintaining the distinctness of these concepts.

If other organizations and individuals endorse these positive activities and help to circulate the publications resulting from them, or undertake in their own ways to educate the public, the result will be a gradual increase in general awareness of the reasons for taking pains to protect verbal artifacts and to keep them in libraries of all kinds, community as well as academic. There will be a greater recognition that the choice between printed and electronic texts is not a question of personal preference but of primary evidence, and that the real issue is determining *which* printed text or *which* electronic text is the appropriate one for a given purpose. Obviously, some verbal artifacts, like some artifacts of every category, will be lost to the vagaries of time, chance, and human energy, and no one can realistically expect them all to survive. The realization that every one of them, however, has its role to play in the study of human culture provides a necessary grounding for thoughtful library decision making. Although the fallacious notion that texts are easily extractable from their physical embodiments is unlikely to be fully eradicated, there is the possibility of a considerably better informed public than has previously existed. Broad public understanding is a prerequisite for the demand, and in turn the funding, necessary to make preservation a goal fully compatible with conversion. Given sufficient public sensitivity to the issues, the two will be seen as complementary necessities, not competing alternatives.

The power exerted by the physical presentation of verbal texts is shown in many ways, such as the ease with which we remember page layouts as we recall certain passages of text, or the figurative use we make of specific book forms as embodiments of knowledge. Melville (in Chapter 32 of *Moby Dick*) used book formats to classify the varieties of whales, discussing the most imposing as

"chapters" of the "Folio Whale" and then moving down to octavos and duodecimos (skipping quarto, because it "does not preserve the shape of the Folio volume" and hence would not be metaphorically appropriate). He later (Chapter 104) spoke of a fossilized Leviathan leaving "traces in the stereotype plates of nature," and thereby reinforced the idea of the world as a book. His frequent puncturing of pedantic commentary further suggests that there is no substitute for reading the book of nature in the original. Reading and writing are a part of life, however, and the objects that contain texts from the past are elements of our physical surroundings. At those times when it is our wish to examine the responses of other people to the world and to the writings they encountered, we must take care in locating the objects most appropriate to our purpose, for reading encompasses all aspects of the objects we choose. We learn something from the folio format (and something else from the quarto), and we learn from all the clues embedded in each set of stereotype plates (be they literal or metaphorical). Caught in a material world, we have no choice but to recognize that the most reliable evidence from the past comes to us in physical objects. The concept of primary sources cannot be separated from this fact. And the search for those sources, in whatever forms they happen to take, is a fundamental activity not only in the work of scholars, lawyers, and scientists, but also in the lives of all other thinking persons.

Print on Demand

Steve Bosch

Administration Department, University of Arizona, Tucson, Arizona, U.S.A.

Abstract

Advances in digital printing have enabled print on demand to support major changes in book publishing and distribution. The ability to print small numbers of titles only when needed by consumers has allowed a huge increase in content to be made easily available in the marketplace. Print on demand has also impacted other areas especially art and artist book publishing as well as music publishing.

Advances in digital printing have enabled print-on-demand (POD) systems to support new channels of book publishing and distribution. The ability to print small numbers of titles only when needed by consumers has allowed a huge increase in content to be made easily available in the marketplace. POD has also impacted other areas of publishing, especially art and artist book publishing as well as music publishing.

POD is the process of creating print products using digital printing technology at the point when needed by customers. The POD process is based on the use of a digital image to directly feed a digital printer that can reproduce the image on the desired media. A single copy can be printed or large print runs can be produced all depending on the customer's need. The digital image can be a wide variety of objects including books, journals, art/photo reproductions, maps, sheet music, etc. Digital printing is also used in the commercial marketplace to produce packaging, brochures, and manuals at the point of need with the flexibility to make minor changes in the materials without reproducing a complete print run.

Based upon the technology first used in copying machines and then prevalent in desktop laser printers, digital printers have progressed far from their humble beginnings and now produce very-high-quality results across a broad spectrum of applications. Digital printing spans a huge variety of systems, from desktop printers for photos to large commercial presses used by companies like Ingrams' Lightning Source. The major differences between digital and other forms of printing are the lack of setup and cleanup required for the digital, enabling the process to produce works as needed. Digital printing has higher fixed costs per copy produced, so there are price points where digital printing is cheaper than offset, but if enough copies are printed, then the setup and clean-up costs are distributed across enough copies to make offset printing cheaper. Digital printing is not yet able to provide the very-high-quality results produced by letterpress

printing, but the high expense of letterpress makes it attractive only to very specialized needs. For larger print runs, offset printing at this time remains the most economical approach, but for small print jobs digital printing has found its niche. It is precisely this ability to produce low-cost small printing jobs that makes POD an agent of change in the publishing industry.

POD impacts publishing in several ways. Foremost, POD enables publishers or authors to print books as needed, which means that books do not have to be printed in large batches and semipermanently warehoused, yet orders can still be fulfilled in a very short period of time. POD also cuts down on transactional overhead that adds costs to book distribution. Prior to POD, books moved through several intermediaries on their journey from the printer to the consumer. Books were shipped from the printer to publishers who then repacked and shipped the books to wholesalers or other intermediaries who then unpack and then repack the books for distribution to retailers, libraries, or consumers. At the retail level, books that do not sell are repacked and shipped back to the wholesaler and eventually publishers. POD removes most of these added transactional costs as only the required items are printed and shipped. Another important consideration, POD is a green technology. It only consumes paper and energy when a book is needed. It has a much lower carbon footprint as the book is shipped once, and by only printing what is needed it avoids pulping unused volumes, again an environmental plus. The digital file is sent from the creator/publisher to the POD supplier and the POD supplier can ship directly to the end customer. Larger POD suppliers can print orders and ship directly to customers within 24 hours of the order's receipt. Customers are provided with the item they want and are not frustrated by messages like, out of stock, back order only, title is out of print, etc. Without costs for added print runs and storage, books no longer have to go out of print. Backlists can produce sales without the added expense of

Fig. 1 Example of a long tail chart.

large prints runs and the need to warehouse the content. POD reduces the cost of book distribution and brings the long tail of publishing into the marketplace.

What is the long tail in publishing? Long tail is derived from the graphical representation of statistical data in which a small number of high-value data points dominates the left side of the graph while a high number of low-value data points dominate the right side of the graph. The chart in Fig. 1 is an example of what a long tail looks like as a graph. For publishing, this translates to a small number of titles produces very high sales while a huge number of titles sell but only at low volumes.

How long tail sales impact publishing has not been verified with quantifiable research, but there are some observable effects. Online retailers like Amazon have probably seen the most benefit from long tail sales. Although the exact sales breakdown between standard commercial titles and long tail sales are not available from Amazon, long tail sales make up a large portion of their commerce. Amazon, and similar online retailers, take metadata about books available for purchase from book data suppliers like Bowker and Nielsen, as well as metadata from wholesalers like Baker and Taylor, and Ingram and populate their online catalogs exposing huge amounts of content to customers. Changes in the industry like the development of POD and electronic books make it possible for retailers like Amazon to list huge amounts of content for sale as it can be easily delivered when ordered. Traditional book distribution systems could not support such a huge catalog as the transactional and storage costs would make it economically impossible to support based on the low volume of sales for the majority of titles in the catalog. POD changes that equation and makes it economically possible to sell huge numbers of titles in low-volume sales.

In addition to carrying other publishers' titles, Amazon provides a self-publishing service, CreateSpace, that assists authors with bringing their work to the marketplace without the need for a publisher. Self-published titles make up a large part of the long tail, and the area has seen

huge growth over the past few years. CreateSpace provides a variety of services from simply printing a set of books, to assistance with the design, editing, marketing, and distribution of both print and electronic books. The service is not limited to book publishing but also provides similar services for music and video producers. Amazon not only profits from the sale of the self-published items, but also produces revenues on the front end by helping authors self-publish their works. CreateSpace is only one of many POD suppliers that can provide authors with a complete suite of services from printing to distribution.

How large is the long tail? In the summer of 2014, Bowker® released a report that describes the size of the U.S. book publishing industry and recent changes in output. The data are based on ISBNs registered. Bowker is the agency responsible for assigning and registering ISBNs. Ebooks are not included nor does the data pick up self-published books that do not register for an ISBN.

The data released for 2013 indicated that the number of titles reported for nontraditional publishing (e.g., self-published, the long tail) was nearly four times greater than the number of titles published by traditional publishers, 1,108,183 titles compared to 304,912. Bowker defines nontraditional publishing as reprint houses specializing in public domain works and presses catering to self-publishers and "micro-niche" publications with these producers marketing their titles almost exclusively on the web and printed on demand. Changes in web commerce and improvement in POD helped the long tail see explosive growth over the past decade. Traditional publishing grew by 27%, from 240,009 titles to 304,912, while nontraditional publishing grew by 4126% from 26,224 titles to 1,108,183. See the full report from Bowker.^[1]

POD has led to some fundamental changes in the book industry. It is now far easier for authors to bypass traditional publishing, both commercial and vanity, and have their works produced and distributed at fairly low costs. Self-publishing has always been an option for authors. There are many great examples of authors who after being rejected multiple times by commercial publishers have

taken the risk of printing a fairly large number of books and selling the titles themselves. The *Huffington Post* covered many of these success stories in a blog by Ronald Balson^[2]. Amazon has a list of top-selling self-published books, and many of these titles were first self-published and then picked up by commercial publishers,^[3] but POD lowers the required investment by huge factors and makes this an option for many authors as the risks are quite manageable.

Traditional publishers benefit from POD as they are able to make their mid and back lists easily available to consumers without having to maintain inventories. POD also reduces their transactional costs as items can be printed and shipped directly to consumers or bookshops without added handling. Traditional publishers can also risk underestimating initial print runs as POD could act as a stop gap, meeting immediate demand after the print run sells out while the publisher considers the need for another offset print run.

The growth in POD has also fueled growth in suppliers. Starting from a handful of suppliers just a few years ago, there are now hundreds of potential suppliers, far too numerous to discuss in a short article. There are websites that provide listings of POD suppliers, one being on the Bookmarket site.^[4] Another site, *An Incomplete Guide to POD Publishers*, compared several of the major POD suppliers' costs and services.^[5] Neither of these sites are complete by any means but they are good places to begin a review of suppliers. There are also many other websites that do comparisons of POD providers. Any good search tool can lead to a wealth of useful information. It is safe to say that practically any large-scale printing house will now offer some form of digital printing services to meet the needs of POD.

Although there are hundreds of POD suppliers and applications, there are some large players in the POD environment that should be discussed. One of the early adopters and one of largest POD suppliers is Lightning Source. Lightning Source, one part of the Ingram Content Group, provides POD services to the largest publishers as well as individual authors. According to the official website,^[6] Lightning Source has more than six million titles in their inventory, processes 27,000 orders per day and prints 50,000 books per day. Lightning Source is an international operation with facilities in Australia, France, Germany, Italy, Spain, and the United Kingdom as well as the United States. As part of the Ingram Content Group, Lightning Source taps into the Ingram distribution chain and can distribute POD content to 38,000 booksellers and libraries including all of the major retailers like Amazon, and Barnes and Noble. Lightning Source is an industry leader and has demonstrated the viability of the POD process as a positive development in book distribution.

Another major player in the POD supply chain is on-demand books (ODB), distributor of the Espresso Book

Machine (EBM). ODB does not market their services as a POD solution. They define themselves as digital to print sales channel that eliminates sales losses due to items being out of stock. Although their business model differentiates them from other POD suppliers, the basic service is still printing a digital object at the point in time needed by a customer. ODBs support a decentralized approach to supplying POD services. Their core business is the sale of the EBM to bookstores and libraries. The EBM is essentially a small stand-alone digital printing and binding installation. The technology is patented by ODB but the printers are actually supplied by Xerox. On demand at the point of sale, the EBM can print, bind, and trim a perfect bound library quality paperback book with four-color cover in a matter of minutes. The EBM cannot supply a full suite of print options, but it does bring POD directly to the end of the supply chain through a bookstore or library. ODBs maintain a catalog of over seven million titles that are available to be printed. ODB also provides software tool set to support self-publishing, and ODB makes it easy for authors to add their works to the online title list making an author's works available to all customers at EBM sites in a matter of minutes. ODB has a complex business model that distributes the proceeds from a book sale to the author, publisher, and EBM owner depending on who is involved with the transaction. Lightning Source does distribute many titles to ODB and also works with ODB self-publishing program to distribute that content through Ingram's digital network.^[7]

Lightning Source and ODB are only two examples of the many POD suppliers that are active in the industry. This is not an endorsement of either company but merely a discussion of what a POD supplier looks like. Lightning Source was selected since they are probably the largest POD supplier. ODB was selected as they bring a unique model to the industry. There are many other quality providers available and information is abundant on the web.

Much of the discussion around POD has focused on book publishing but POD has had an impact in other types of publishing as well. As mentioned earlier, digital printing uses any digital image to directly feed a digital printer that then reproduces the image on the desired media at the point of need. The digital image can be practically any digital object. This could include maps, photographs, sheet music including scores, documents, art reproductions, posters, etc.

Art reproductions and artist books are areas that have seen changes due to the availability of POD. Very-high-end digital printers are capable of making excellent reproductions of artworks, photographs, and posters. In addition, the print jobs can be done in small batches and delivered in short periods of time. POD enables museums and galleries to tailor their printing needs to existing demand as opposed to having to pay to print 5,000 copies of an exhibition catalog and only needing 4,000. The same logic applies to other types of retail items that could be

sold in connection with an exhibition, or any other need, including art reproductions, calendars, greeting cards, etc. These retail items can be ordered based on need, and consequently once demand dwindles, there is no over stock to deal with. POD enables museum and galleries to offer far more works to their customers since they avoid the costs of large print runs and storage of the items awaiting sales. Web commerce can expose the digital catalog to consumers, and at the point of sale, the item can be printed and sent to the buyer.

Artist books have been similarly impacted by the development of POD. In the late 1960s and early 1970s, artists were experimenting with creating books as works of art. Many of the artist's books were completely unique one-of-a-kind creations, and those are outside this discussion. However, many other artists' books were a fusion of text and graphics and these were printed and distributed. With traditional book distribution channels, creativity was hampered by the need to print fairly large amounts of books that had a very limited audience. With POD, artists, designers, architects, and photographers are now able to produce work at the scale needed, and in some areas like photography, new areas of creative work opened up. Nearly all weddings, or similar major social events, are now documented in books that accompany the photos of the event. The creation of senior portraits is seeing similar developments. The digital images are used to produce photos, books, and graduation announcements, all of these products enabled by POD. Traditional printing methods would be far too expensive to allow for a whole suite of customized products at a personal level. If anyone you know has recently been married, baptized, graduated from school, or you just happen to know a photo enthusiast, you probably have one of these books somewhere in your house—brought to you by POD.

Music publishing, like other areas, has seen new opportunities due to the availability of POD. Digital distribution of sheet music and scores has not become the standard distribution channel. It may be that trying to balance laptops or tablets on sheet music stands in the orchestral pit is not yet workable, and the killer app for sheet music has not come to market like the e-reader for ebooks. Music publishing like traditional book publishing has similar issues surrounding the warehousing and distribution of printed works. Works have been traditionally printed in fairly large runs and then distributed through channels to various retail outlets. Once a score goes out of print, the high cost of another print run frequently precludes a new printing and the score then becomes very hard to locate and acquire. A parallel exists between music and book publishing. Using POD and avoiding the costs for added print runs and storage, scores no longer have to go out of print. Music publishers' backlists can produce sales without the added expense of large prints runs and the need to warehouse the content. POD reduces the cost of music distribution and enables consumers to obtain sheet music and scores that were previously not available.

POD has created many opportunities for authors. There are now many entrance points to the marketplace and a variety of ways to have your work published without going through a commercial or vanity publisher. There is a huge spectrum of POD suppliers. Many will provide a minimal service and print whatever number of items you request. It may be 5 copies, it may be 500. Others suppliers will provide the author with a complete suite of services including editorial, design, and layout assistance, as well registration of the book to obtain the ISBN and provide marketing and distribution assistance. These added services all come with a price, but for many authors the price is worth getting their work to market. The major consideration for most self-publishing authors, there is no rejection notice from the POD provider. POD has opened up self-publishing, and consequently, there is now a huge number of books available for consumers to choose from.

Authors now have much to think about as they decide how to put their work forward. Do they go the route of a commercial press or publish on their own. If they got the route of the commercial press, they have to consider what rights they will sign away. Since their work may not go out of print, authors need to consider the impact of the terms of the agreement concerning the life of the work since for some titles, especially textbooks, authors may be asked to agree to not publish competing works. Similarly, authors have to be careful what they agree to as they sign self-publishing agreements. With the advances made in POD, authors and publishers now have many more choices about their product and the product's distribution than were available with traditional publishing and distribution systems.

POD is no longer a trendy new upstart. Many of the major businesses involved with book distribution have brought their version of POD services to market. The two major book retailers have POD services, Amazon supports CreateSpace and Barnes and Noble supports the Nook Press Program. Ingram launched Lightning Source and Baker and Taylor has textstream, which is a POD service delivered through a partnership with Bookmasters. Large printing houses like R.R. Donnelly have also launched POD/digital print services. In addition to these industry leaders' investment in POD, there are a huge numbers of smaller suppliers who offer competitive services to potential authors and small publishers. The nature of authorship is also changing. It is now common for significant social events to be recorded and "published" in books. The wedding album is fast becoming the wedding book. Even for those with no special skills, it is possible to take a series of digital photos, drop them into a template, add a few lines of description, and they have a book they can print and send to their friends and family. As long as consumers are interested in physical objects, there will be a market for printed objects. POD lowers the costs and entrance barriers to that market. The development of the on-demand supply chain goes together with the development of the long tail in retailing. They make each other possible.

POD opens up new market space for creators but who prospers in that market space remains to be seen.

Private Presses and Fine Printing [ELIS Classic]

Roderick Cave

Loughborough University, Loughborough, U.K.

Abstract

Cave, an expert on private presses, surveys several types of private presses, and includes a discussion of printing as a fine art.

—*ELIS Classic*, from 1978

INTRODUCTION

The term “private press” has been used by historians of printing from the mid-seventeenth century onward to describe a variety of printing or publishing establishments outside the normal run of printers active in the period or in the society in question.^a In a totalitarian society, for example, any press not directly under state control might be regarded as a private press; but, this press, its *raison d’être*, and its publications will all be very different from those that are often (in the English-speaking world) regarded as the only private presses: those of the kind that regard the making of books as an art form.

One can trace the development of presses that are outside the normal pattern of printing and book production right back to the invention of printing from movable types in fifteenth-century Europe or even beyond: The manuscripts produced in the scriptorium of the Florentine scribe Vespasiano da Bisticci, for example, can, in more senses than one, be regarded as the ancestors of the modern “fine books” in the production of which the private press movement has played so large a part.

ORIGINS

After the invention of printing at Mainz, printers spread rapidly to the main mercantile and academic centers of Western European life. In the large centers, where the local demand was sufficient, printers could maintain themselves by their trade without outside assistance. But in smaller towns with a lesser local market, or in less settled parts of the world, there was insufficient work to keep a printer employed or to attract him there in the first place. In such circumstances, many presses that one must regard

as private grew up. In Chartres, for instance, a canon of the cathedral, named Pierre Plumé, in 1482 invited the Paris printer Jean du Pré to come to Chartres to produce a missal for the cathedral’s use, and he installed du Pré and his equipment in the canon house while it was being printed. A Chartres Breviary was produced in the same way in the following year.^b

THE QUASI-OFFICIAL PRESS

A distinct category of private press is to be found in those establishments financed and controlled by rulers and other wealthy patrons to produce work at their behest. Almost the first ruler to recognize the propaganda value of the printed book was the Holy Roman emperor Maximilian I. By appointing Johann Schönsperger the elder as court printer and by ordering the production of the emperor’s prayerbook (1512–1513) and the *Theuerdank* (1517)—which glorified the exploits of the House of Habsburg in general and of Maximilian in particular—the emperor was controlling a press that was undoubtedly private. But it was also the forerunner for many prestige items produced by government printing houses, such as the Imprimerie Royale’s *Médailles sur les principaux événements du règne du Louis le grand* (1702).

Rather similar in character were the presses that were established in less settled parts of the world. The introduction of printing into Iceland, for instance, followed the Chartres pattern closely when, in 1530, the last Catholic bishop of Hoolum organized the establishment of a press that produced a *Breviarium Nidarosiense* in the following year. That the press was not regarded as an undesirable eccentricity is shown by the fact that the bishop’s Lutheran successor continued to give employment to his printer, Jon Matthiesen. Without such patronage, it is most unlikely that any printer would have set up in Iceland at

^aThe earliest writer to distinguish private presses was Bernard Mallinckrodt, in his *De ortu ac progressu artis typographicae dissertatio historica* (Cologne, 1639). The earliest extensive treatment of private presses was given by Adam Heinrich Lackman in *Annalium typographicorum* (Hamburg, 1740), of which a modern English version remains a desideratum in private press literature.

^bThe references for this and the later examples given in this article are to be found in Cave.^[1]

this early date. In many respects, the mission presses in Asia, Africa, and the South Seas—often as amateur in their operation as they were uncommercial in their aims—were the successors of this early variety of private press.

THE SCHOLARLY PRESS

A type of amateur press that has recurred time and time again is one that is established with the prime purpose of printing works of scholarship. This was, of course, sometimes undertaken by presses of the quasi-official or patron's kind—The production of the great *Complutensian Polyglot Bible* at Alcalá in Spain is the best instance of this type of work, and it cost Cardinal Ximenes some 50,000 gold ducats (a sum roughly equivalent to \$3–4 million dollars in today's terms).

Some of these scholarly presses were clearly filling the role that would later be taken by the typewriter and the mimeograph. Such was the production of a private edition of Archbishop Parker's *De antiquitate Britannicae ecclesiae*, which the Elizabethan printer John Day printed for him in Lambeth Palace so that the archbishop might always have a copy by him to amend the text as need arose. Cardinal du Perron is similarly credited with a press at his chateau de Bagnolet in France, which was used to print preliminary drafts of the cardinal's works. After these had been circulated (for comments and criticism) to a select group, the text would then be revised for general publication.

Most scholarly presses were not set up as aids to composition in this way, but rather to supply needs that the ordinary commercial printers could not handle. In the publication of astronomical work, for instance, where absolute accuracy is essential, it was not uncommon for the astronomer to have his work printed in his own house under his direct personal supervision: Regiomontanus, Hevelius, and (in particular) Tycho Brahe adopted this method for their books.

Tycho Brahe's press is particularly interesting. In 1576, he had been granted the island of Hveen by the king of Denmark and had built an impressive observatory there. Finding that Copenhagen printers could not meet his exacting requirements and that he was too remote from the better craftsmen in Germany to have his work produced there, he imported presses, type and other equipment, and a printer, and set up a printing office as an adjunct to his observatory. Subsequently, when paper supplies proved inadequate, he added a paper mill to his operations. With this equipment, some of the most significant work in the history of science was produced.

Another area of scholarship in which the normal commercial printer was often inadequate was in language studies. Many of the special typefaces needed for printing in exotic languages had their origin in private commissions.

The Anglo-Saxon type used for Elizabeth Elstob's *Anglo-Saxon Grammar* in 1715, and the type cut by Charles Wilkins for his *Grammar of the Sanskrita Language* (1808) are examples of such private typefounding, although in both cases the books were printed commercially. Another "linguistic" press was that operated in London by Prince Louis-Lucien Bonaparte in the 1850s. This printed texts from St. Matthew in a variety of Basque dialects, a specialized area of work in which the old advantages of having a printer under the scholar's direct control are obvious. But by that time, much of the need for a private scholarly printing house had disappeared: With the growth of academic publishing and of printing houses specializing in particular languages, it was perfectly possible for a scholar to have work printed, in Cambodian, Cree, Catalan, or what you will, without setting up a press of his own. Yet the private scholarly press is not dead, as will be seen below.

THE EDUCATIONAL PRESS

The advantages of a small printing establishment as an aid to education were widely recognized in ruling houses in Europe by the eighteenth century. Such did not call for a permanent establishment, of course a visit by the young Louis XIV to the newly established Imprimerie Royale in 1648, during which he "helped" with the production of an edition of the *Mémoires* of Phillippe de Commynes, or the occasion on which, in 1731, the London printer Samuel Palmer set up a press in St. James's Palace so that the royal children could try setting up type—these are instances of the many occasions on which children of the ruling classes were exposed to the "black art." In a few cases, however, special permanent printing rooms were set up: Both Louis XV and Louis XVI as children had small presses on which they (with assistance) printed a few small books and no doubt more easily learned the texts they were setting up.

THE ARISTOCRATIC PLAYTHING

In the eighteenth century, printing also developed as a hobby among the wealthier and more leisured classes. Such had been advocated in England by the newspaper *The Craftsman* in reporting Palmer's work in St. James's Palace in 1731: "We could wish that our *Nobility* and *Gentry* would follow this Royal Example, and set up a *Printing Press* in their Houses; which. . . would be a much more polite as well as a more instructive Amusement for Themselves and their Heirs, than the modern fashionable Diversions of *Billiard Tables* and *Foxhunting*." Few of the English aristocracy took *The Craftsman's* advice, though it was certainly known to Horace Walpole, owner of the Strawberry Hill Press (q.v.). During its 32 years of life, from 1757, the Strawberry Hill Press produced several

books of real importance, as well as a good deal of ephemera (complimentary verses in honor of visitors, guides to the contents of the house, and the like). Walpole's comment that the Strawberry Hill books "have all the beautiful negligence of a gentleman" typifies the spirit of these presses.

On the continent, many such playthings existed. The duchesse de Bourbon-Condé had a press in the Palais de Bourbon in 1730; at Versailles, the duc de Bourgogne, Madame de Pompadour, and others were all printing in the 1760s and 1770s; while many of the aristocracy—the marquis de Lussay, the duc de Choseil, Président Saron, and others—had presses in their own châteaux from which they issued volumes of memoirs, family histories, and the like. Most of this work was of little general interest, but two exceptions must be noted. The press of Caperonnier de Gauffecourt in 1763 printed the first manual on book-binding ever to be published separately, while, in the 1780s, Léorier de Lisle printed two books on papers made from nettles, mallow, and other fibers new to the papermaker's craft.

Far more substantial and serious in intent than most of these was the press "au donjon du château," which Frederick the Great of Prussia operated from 1748 until such things were brought to a halt by the outbreak of the Seven Years' War. As well as producing Frederick's own *OEuvres du Philosophe de Sans Souci* (1750), it printed Frederick's history of the House of Brandenburg, for which Voltaire acted as reader, and—unusual for such hobby-presses—a manual on military tactics for distribution to the Prussian general staff.

The French Revolution and the Napoleonic wars tended to dislocate, if not to stop, the activities of all private presses of this kind on the continent. In Britain, however, they gained a new lease on life from the fashion for book collecting, which went through a boom period in the early nineteenth century. Several collectors started presses with a more scholarly purpose than the playthings of the preceding century: to put into print manuscripts never before printed and to reprint very scarce works. Such presses as the Hafod Press of Colonel Thomas Johnes, or Sir Egerton Brydges's Lee Priory Press, or Sir Thomas Phillipps's Middle Hill Press served as forerunners to the publishing societies such as the Roxburghe Club and Hakluyt Society, whose work was to be important later in the century.

THE MIDDLE-CLASS HOBBY

Although the educational advantages of printing and the pleasure to be derived from it as a spare-time occupation were already clear in the eighteenth century, only persons with considerable means could afford the very heavy outlay involved in setting up a full-scale printing office. Until iron presses were developed at the beginning of the

nineteenth century, there was no really practicable way of miniaturizing printing equipment. Nearly all the private presses mentioned above were operated with the assistance of full-time paid personnel: Few indeed of the French aristocrats undertook the heavy work of operating their presses themselves. But in England, where the introduction of iron presses had been pioneered by Lord Stanhope in 1800, miniature printing outfits were being marketed from the 1830s onward for "the amusement and education of youth." In the United States, where the first press to cater specifically for the amateur market was introduced in 1857, the movement took a radically different form. The first advertisement of William A. Kelsey (whose firm at Meriden, Connecticut, still produces presses for the amateur market) emphasized its commercial advantages: "Business Men save expense and increase business by doing, their own printing and advertising. For boys, delightful *moneymaking* amusement."

Between Victorian high-mindedness and Yankee entrepreneurship, there was a very wide gulf, but between them was created a real craze for printing as a hobby. From Rudyard Kipling to Thomas Edison, from Robert Louis Stevenson to "Little Lord Fauntleroy" himself, one finds instances of people playing with printing. Most of these amateurs produced little of interest to other than their own immediate circle of friends (an exception being the Daniel Press, q.v.). By the end of the nineteenth century, the craze for printing had largely been superseded by other hobbies such as photography, and only those "back bedroom" amateurs who were following Kelsey's advertising and irritating the printing trade with their production of letterheads and other jobbing work at cut rates continued work.

THE AUTHOR AS PUBLISHER

This group fits uneasily into the categories of private presses already listed above. The man who buys a printing press in order to print his own work may do this (rather than employing commercial printers) because it is more rewarding financially: In Britain, a lawyer, Charles Viner, and a physician, John Hunter, both ran presses that were very profitable in the eighteenth century. More commonly, authors set up as their own publishers because they cannot sell their work to commercial publishers and cannot afford the rates charged by vanity presses. The supreme instance is of William Davy, a Devon clergyman who, between 1795 and 1807, printed his *A System of Divinity* in 26 thick octavo volumes. In its production, the only assistance he had was from his housemaid, whom he taught to set type.

In most cases, to get an author's texts into print was all that was required of such printing, no matter how badly it might be executed. But there were and are private presses operated by authors who choose this method for deliberate aesthetic reasons: where an author has felt that only by his

personal design and decoration of the book that was to be the vehicle for his texts could the full intention of his work be realized. The exemplar for such work is to be found in the “illuminated” books printed by the artist/poet William Blake. Blake towers so far above most others who have attempted work of this kind that it is all too easy to forget that he *was* operating a private press—an extremely influential one. Among the enormous number of those inspired by his work and who have attempted work in the same tradition are a few that deserve mention, such as the Iona Press in the 1880s, or the work of Ralph Chubb from the 1930s to the 1950s, or today, Morris Cox’s important Gogmagog Press in London.

CLANDESTINE PRESSES

Private printing establishments have, of course, flourished in secret ever since man discovered the power of the printed word, whenever there has been political, religious, or moral oppression. In Elizabethan England, for example, one finds instances of clandestine presses at both ends of the religious spectrum: in the work printed by the Catholic martyr Edmund Campion on the one hand, and in the Puritan “Martin Marprelate” tracts on the other. Or—to take another instance from a country with a long tradition of freedom of the press—the seizure of the private press operated by the English politician John Wilkes in London in 1763 (a seizure ostensibly on moral, but, in fact, on political grounds) is a classic case in British constitutional history.

Sometimes called “underground presses,” such clandestine operations have occasionally been literally that, like that of the Abbé François Xavier de Feller at the end of the eighteenth century, which produced anti-Austrian propaganda from the bottom of a coal mine near Liège, while the police of the Austrian Netherlands vainly sought it. But normally “underground” refers only to the presses’ clandestine status (and this has, in any case, been devalued as a descriptive phrase by its misapplication to presses espousing minority causes and an alternative society, which are not in danger of suppression at all). These clandestine presses flourished in Ireland during “the Troubles” and in prerevolutionary Russia (and since: the *samizdat* editions, which figure in contemporary Russia, are the direct descendents of earlier endeavors against censorship); and they were by no means the least important aspects of the resistance to Nazi occupation in Europe in World War II. In both France and the Netherlands—and only to a lesser extent in Poland, Denmark, and other occupied countries—there were extensive illicit printing enterprises carried on by amateurs in the 1940s.^c Some of the work produced was of very high literary and typographic quality, but with the twentieth-century development of easy photocopying and office duplicating methods, such illicit work is nowadays more often carried out by such simpler methods rather than by letterpress printing.

There are other private presses that are clandestine in their work for less high-minded reasons than those that inspire the operators of the presses named above. In the stricter moral climate of the past, the printing of erotica such as *Fanny Hill* was attended by such penalties that it tended to be produced by clandestine printers, as today hard-core pornography is still so produced. And for those who interpret the Kelsey Company’s advertising slogan “Print—make money” too literally and turn to counterfeiting, the role of the clandestine printing plant is vital.

There are other private presses that are clandestine in their work for less high-minded reasons than those that inspire the operators of the presses named above. In the stricter moral climate of the past, the printing of erotica such as *Fanny Hill* was attended by such penalties that it tended to be produced by clandestine printers, as today hard-core pornography is still so produced. And for those who interpret the Kelsey Company’s advertising slogan “Print—make money” too literally and turn to counterfeiting, the role of the clandestine printing plant is vital.

PRINTING AS A FINE ART

The twentieth-century private press movement and its association with the production of “fine books” is to be traced back to the establishment of William Morris’s Kelmscott Press (q.v.), which was in turn inspired by a lecture given by Emery Walker (q.v.) to the Arts and Crafts Exhibition Society in 1888.

The work of such presses is discussed in the previously published, print version, of this encyclopedia (*see* Ashendene Press, Vol. 1, pp. 662–665; T.J. Cobden-Sanderson, Vol. 5, pp. 224–231; Daniel Press, Vol. 6, pp. 425–428; Doves Press, Eragny Press, Vol. 8, pp. 161–164; and Kelmscott Press, Vol. 13, pp. 407–415). Their function, so far as they understood it, was to reestablish sound principles of book *design*, which, during the nineteenth-century mechanization of the printing trade, had not kept pace with the technical advances of the period. These presses attempted it usually by returning to first principles: to the standards in design and execution to be found in the finest fifteenth-century Italian printing as a rule, although in some instances other models were adopted, for example, the Daniel Press’s revival of seventeenth-century types.

With hindsight, it is possible to discern many mistaken routes taken in their quest for the “ideal book”: the gothicising element in Kelmscott work, the frigid classicism of Cobden-Sanderson. By tying their work to the ideals of hand craftsmanship and “truth to materials,” which were so important to those in the Arts and Crafts Movement, they did not form good examples for commercial book production. Those trade books that were produced early in the twentieth century under direct private press influence were not seldom ugly and ineffectual vehicles for an author’s words. Nevertheless, the fact that work of Kelmscott, Doves, and other private presses was successful in redirecting attention toward book design—in making it a subject about which the ordinary educated

^ccf. Dirk de Jong, *Het vrije boek in onvrije tijd* (Leiden, 1953); and “Vercors,” in *Voices of Silence* (London, 1968).

man could be expected to be aware—was a major step forward.

During the years between the two world wars, the lesson of the private presses was successfully applied to trade book production. The work of professional typographers like Bruce Rogers, W.A. Dwiggins, and Stanley Morison (allied to the revivals of good type designs of the past by manufacturers of composing machines) was of particular importance in this respect. No less important were the publishing imprints, the Nonesuch Press and the Limited Editions Club, which showed that it was possible to produce books of excellent design and fully up to the standards of workmanship of the old private presses, while using the mechanized equipment of modern commercial printing houses. There was also the growth of small commercial printing houses that worked in the tradition and to the standards of the private presses. Such printers were to be found in many locations (a famous example being Will Carter's Rampant Lions Press in Cambridge, England); but these were to become a particular feature in California, where the work of such printers as the Grabhorn Press, the Plantin Press, and Ward Ritchie is justly of high reputation.

At the same time, many private presses much closer to the Kelmscott tradition continued to produce fine work, particularly in Germany, the United States, and in Britain. One may, for example, cite the Shakespeare Head Press, or the Golden Cockerel Press (q.v.), which was particularly important for the part it played in the revival of wood-engraved book illustration. In France, the influence of the arts and crafts movement had never been strong, and the French *livres d'artiste* were produced with different ideals in view from the private press credo, though similar in some respects to good private press work.

THE CONTEMPORARY PRIVATE PRESS SCENE

Although several of the important private presses continued operations in the 1940s (particularly, of the course, in the United States), World War II and the years of austerity that followed it in Europe almost destroyed the market for expensive books of the traditional "fine printing" kind. The era of the deluxe book seemed to be at an end, and obituary notices for the private press were commonplace in the early 1950s. However, just as the past quarter-century has seen the steady decline of commercial letterpress printing before the advances in offset lithography, so the same period has witnessed a recrudescence of private presses (most of which are devoted to letterpress work), so that today there are more amateur printers active than ever before.

The spirit that imbues the contemporary private printer is very different from that of the parlor printers of the nineteenth century. Today's amateurs are bibliographically well informed, being brought up on the typographic

literature of D.B. Updike, Stanley Morison, and others, and, in consequence, they are able to practice their spare-time avocation with a taste and skill seldom possessed by their nineteenth-century predecessors.^d

There are many private presses whose proprietors devote themselves mainly to amateur journalism, producing (sometimes as a collective venture) many hundreds of little magazines. Occasionally, these will print material of literary importance, but more usually their work is produced with a deliberately lighthearted ephemeral content, which renders it of limited interest outside their own immediate circle.

In contrast, one can, among today's private presses, distinguish many that work directly in the traditions of earlier varieties of the private press and that publish matter of much more weight and general interest. Their work, of which a substantial proportion is listed in the Private Libraries Association's annual bibliography *Private Press Books* (1959–), falls into several different (though not mutually exclusive) groups:

1. *The typographic presses*, which exist primarily to produce experiments in design, layout, and so forth. John Ryder's Miniature Press, or the Cuckoo Hill Press of David Chambers, or the Tuinwijkpers of Sem Hartz are good instances of such private presses. To an increasing extent, some of these are allied to a new hobby, that of the amateur typefounder. Such private printers as Paul Hayden Duensing at Kalamazoo, Michigan, have not only produced new castings of typefaces that have disappeared from the repertoires of commercial founders but have also originated some very effective new designs, some of which have been pirated for the commercial market in exactly the way that the Kelmscott Press's types were commercially imitated.
2. *The scholarly presses*, which print important texts of limited appeal, for which the normal commercial or academic publisher may not be well suited. In England, Geoffrey Wakeman's Plough Press—with its portfolio on *Nineteenth Century Illustration Processes* (1971), which was illustrated with leaves from nineteenth-century books that had used the processes described—is one example of the genre. In the United States, there are: Henry Morris's distinguished series of books on papermaking from his Bird and Bull Press; or from the Press of John Cumming in Mount Pleasant, Michigan, several substantial volumes of Michigan history; or from Charles Ingerman's Quixott Press in Doylestown, Pennsylvania, some studies on local Quaker history—these are representative of the valuable work published by contemporary amateurs.

^dWith the aid of such excellent manuals as Dobell^[2] and Haas.^[3]

3. *Fine art presses*: these are normally working directly in the tradition of William Morris and the private press movement in attempting to build books of typographic excellence as vehicles for worthy texts (though some, like the Allen Press in Kentfield, California, span the gap between the private presses and the French *livres d'artiste*). These range from Alan Tarling's modest "Poet and Printer" in Essex, England (which is content with unassuming texts for sale at a low price), through the severely classical and exquisitely produced work of the Nuns of Stanbrook Abbey Press (Worcester, England) and that of Kim Merker at the Stone Wall Press in Iowa City, through the less classical but equally splendid Janus Press books produced by Claire Van Vliet in Vermont, to the extraordinary work of Walter Hamady at the Perishable Press in Wisconsin. Perishable Press books, often printed on paper made at the press, have, at times, broken every typographic rule there is and are, at times, unsusceptible to adequate bibliographical description—yet they remain some of the liveliest and most exciting volumes of contemporary poetry.

Some presses transcend these categories, of course. In England, one of the most interesting private presses is that of Trevor Hickman, the Brewhouse Press in Leicestershire. Some of its books have been serious contributions to scholarly knowledge, whether typographic (*Typographia Naturalis*, a history of nature printing) or local history (*The Oakham Canal*); others are exercises in fine illustration (*The Pickworth Fragment*); yet other productions will be lighthearted ephemera or typographic experiments. This press is by no means unique in its range and styles of work; though producing more and often better work in the various fields in which it operates, it typifies much that is best in the private press of today.

The presses range as widely in equipment and scale of operations as in the types of work they issue. Some of them are virtually working museums, keeping in use presses built a century and more ago, and preserving techniques of craftsmanship that would otherwise be lost. Some, though still devoted to the use of the best materials, prefer to employ more modern presses in order to be able to produce long runs of high quality with less labor. Yet others will be very small indeed; a small flatbed press that can be stored under a bed, plus enough type to print a page at a time, will be the sum total of their equipment.

BIBLIOGRAPHICAL PRESSES

An interesting and significant development from the private presses has been the appearance of *bibliographical presses*.^[4] Schools of art that teach courses in graphic design have, of course, for long had printing equipment

on which student work was produced. Porter Garnett's famous Laboratory Press in Pittsburgh (1923–1935), and the Lion and Unicorn Press of the Royal College of Art in London are among the best known of these, and they have produced a considerable volume of important work prized by discerning collectors. The bibliographical presses, on the other hand, are working laboratories set up to assist the bibliographical student to an understanding of book production methods, through personal experience in setting, presswork, and so forth. Presses of this kind are to be found sometimes in university libraries (as at Bodley, McGill, or Sydney), sometimes in English departments, and often in schools of librarianship. In the nature of things, their productions tend to be slighter and more ephemeral, but they have also produced a generation of literary scholars and librarians whose understanding of the niceties of printing is much greater than a generation or two ago.

"LITTLE" PRESSES

The "little" presses may be regarded perhaps as an offshoot of, perhaps as a rival to the private press movement. These undertakings—the publishing industry of an alternative society—are not in general very much interested in typographical excellence: They exist in order to put into print works that their owners feel passionately *should* be published and that, for one reason or another, are unsuitable for the commercial publisher. Particularly active in the production of literary magazines, experimental poetry, and work of a kindred nature, they span the gap between the amateur and the full-scale publishing operation. At one end of the scale (because of their concern with the text rather than its presentation), they may produce their pamphlets by office duplicating processes; at the other, they may be semi-commercial publishing imprints having all their printing done for them by others. Advances in small offset litho printing have meant that many of these little presses will employ such techniques for their work rather than the letterpress printing favored by most other private printers. With a successful public response to their literary programs, they may become almost indistinguishable from the ordinary commercial publisher, with the important proviso that they remain more interested in producing what they think is good work than in maximizing profits (which is true of the better commercial publishers also, of course). The Unicorn Press in California and the Gaberbocchus Press of London are good examples of the species.

THE FUTURE OF THE PRIVATE PRESS

It is a commonplace that changes in the structure of the publishing industry, and in printing technology, have

produced a situation in which the book that is of limited appeal or is a slow seller is much less likely to achieve publication than was formerly the case. In consequence, a book of merit, one that will appeal only to a minority group, will not in the future be published unless subsidized by a learned society or other body or if the amateur publisher takes an active role. To be sure, some unprofitable publishing areas will be catered for through the programs of scientific journals, publishing societies, and the like. But in the fields of imaginative literature and local history (in its widest sense), there is a distinct gap that can be filled only by the concerned group or individual enterprise.

The little presses can cater for some of society's needs in this way. Similarly, the traditional private press will continue to produce work for those who feel that the book can and should be more than just a vehicle for the texts they contain (or that on occasion the vehicle should be a Rolls-Royce rather than a Detroit production-line job). At present, there is too wide a gap between these two kinds of private press: though it may be unrealistic today to expect that private press ideals of craftsmanship can be carried over into normal commercial book production, many of these ideals could advantageously be applied by the little presses. In the same way, the little presses' concern for the texts they print would render more permanently valuable the work of those private printers who demonstrate great taste and skill in printing rather negligible texts.

CONCLUSION

There is no doubt that the increase in the number of amateurs producing books and literary magazines presents many problems for the librarian. A good deal of the work they print may technically not be published (in the legal sense) at all and so escape record in those national bibliographies that are based upon legal deposit. Being produced outside normal book trade channels, their work may not be listed in the standard trade bibliographies and will seldom be carried in the stocks of booksellers and library suppliers. In consequence, the librarian concerned with selection of stock will have difficulties in finding out about these publications. In addition to this barrier (which requires perseverance on the librarian's part to overcome), there is also, at times, a consumer resistance, on the librarian's part, to the purchase of material that may occasionally be very awkward to process, store, and make available to readers (how *does* one shelve a book that opens concertinawise? or one triangular in shape?). The puritan ethos that imbued many earlier librarians also made them reluctant to buy some of the rather luxurious (and expensive) private press work of the past. For these various reasons, one often finds that private presses' work

is less widely distributed in public libraries than one might expect.

Some libraries deliberately cultivate good relations with those amateur printers/publishers active in the area they serve and build up an archive of the press's work (ephemera as well as books), which—although difficult to handle—has important long-term cultural significance. In addition, some research libraries built up substantial collections of private press material: the Eric Gill collections at University of California at Los Angeles, the Will Ransom collection in the Newberry Library, Chicago, and the Bodleian Library's collections are of particular importance in this way. But in general, professional librarianship's attitude to private press work has been one of lip service and little more: with the purchase of a few representative Kelmscott, Golden Cockerel, or Grabhorn books to grace the library's display cases, the librarian has assumed that he has performed his function adequately. But, given the increasing importance of much published by these amateur printers and publishers, unless librarians succeed in improving their coverage of private press work, posterity will judge their professional competence harshly.

Provenance of Archival Materials

Shelley Sweeney

University of Manitoba, Winnipeg, Manitoba, Canada

Abstract

Historically, the principle of provenance was defined to mean that archivists must not mix the archival records of one person or organization with that of another. Sometimes this principle included respect for original order, which meant that records must be kept in the same order as maintained by the creator. In order to assign provenance, however, archivists needed to define the provenancial unit or the volume and level of records that would be described by provenance. This would be used as the basis for appraisal, acquisition, arrangement and description, retrieval, and reference. This definition was, and continues to be, problematic. Originally, the principle of provenance applied to both the physical and theoretical handling of records in an archives, but more recently archivists have suggested that provenance is a theoretical construct and that description based on provenance must capture all the myriad aspects of the origins of the records from the context of their use in the active record-keeping system to their transfer and handling in the archives. Since the inception of the principle of provenance, archivists have debated every aspect of it. The principle only gets more complex with time and the question becomes: how can these complex notions be applied in the real world?

INTRODUCTION

Provenance is considered to be a foundational principle of archival science, particularly in the Western world. It is the basis for acquiring, appraising, arranging, describing, and accessing archival records, or in other words, deciding what to acquire, how much to retain, whether to organize the records or leave them in their original order, how to describe the records, and how to find useful records. Provenance is also the means for establishing the authenticity of records and often can be used to date them. There is, however, disagreement among archivists and in the archival literature about what exactly constitutes provenance, how it can be attached to records, and how to apply provenance to various archival functions. Given this principle's importance to the practice of archival science and the complexity of its application, it is likely that the concept will continue to be further defined and refined in the future.

This entry covers the established definition of provenance, the origins and history of the development of the concept, the meaning of provenance, and the modern-day expansion of the principle. Readers will come to understand why, as French theorist Michel Duchein said, provenance "is easier to state than to define and easier to define than to put into practice."^[1]

THE DEFINITION OF PROVENANCE

According to the International Council on Archives (ICA) *Multilingual Archival Terminology*, the word provenance is defined as being "the organization or individual that created, accumulated, and/or maintained and used

RECORDS in the conduct of business prior to their transfer to a RECORDS CENTRE or ARCHIVES." The ICA Committee on Descriptive Standard's "Glossary of Terms Associated with General Rules" adds that it is also the relationship between records and the organizations or individuals that created, accumulated and/or maintained, and used them in the conduct of personal or corporate activity.^[2] The principle of provenance means that "records/archives of the same provenance must not be intermingled with those of any other provenance."^[3] There is an equivalent term for provenance: *respect des fonds*. The term *fonds* refers to the records created and accumulated by an individual, family, or organization in the conduct of their personal or corporate activity. So *respect des fonds* then means to respect these records by not intermingling them.

There is also the concomitant principle of original order, or *l'ordre primitif*, which according to the *Multilingual Archival Terminology* states that "archives of a single provenance should retain the arrangement (including the reference numbers) established by the creator in order to preserve existing relationships and evidential significance and the usefulness of finding aids of the creator."^[4]

THE ORIGINS AND DEVELOPMENT OF THE CONCEPT

The Inclusion of Original Order and the Definition of the Provenancial Unit

The earliest documented origin of provenance was traced by Spanish archivist Rosana de Andres Diaz to the *Instruccion para el gobierno del Archivo de Simancas*

published by Philip II in 1588, which applied the principle of provenance to the arrangement of title deeds.^[5] E. Lodolini has traced the practice, if not the principle, back to the archives of Republican Rome.^[6] American archivist Maynard Brichford brought to light the provenancial nature of the work of French Maurist scholar and Benedictine Dom Jean Mabillon. Mabillon's publication, *De re diplomatica libri sex*, published in 1681, established the science of diplomatics and paleography. His treatise on textual criticism and the authentication of documents directed attention to the source of records by employing detailed studies and comparisons of documents issued by the same chancellery.^[7]

Mabillon's pioneering work was followed, Brichford noted, by diplomatic manuals employed by history professor Johann Gatterer at the historical institute that he founded in Göttingen, Germany, in 1764. These manuals similarly linked documents to the administrations that created them. According to Spanish archivist Antonia Hereñia Herrera, archives were following the principle of *respect des fonds* in such diverse places as Halle (Saxony) in 1777, Denmark in 1791, and Naples in 1812.^[8] Others have noted that the principle was legislated in the Grand Duchy of Tuscany in 1822 and the Papal State in 1839.^[9]

These early forays into the theory and practice of provenance were supplanted in the nineteenth century by a new enthusiasm for subject arrangement. The practice of reorganizing records from different creators to fit subject classification schemes evolved into the principle of pertinence. There are many possible explanations for this interest in subject classification. Some of those employed in archives, such as Gottlieb Friedlaender, an archivist who worked in the Prussian State Archives from 1853 to 1873, were influenced by their library experience.^[7] A number of authors have pointed out that during the European Enlightenment many scientists employed classification schemes to validate their pursuits and that this possibly provided a basis for the employment of such classification schemes in archives.^[10]

But perhaps the most significant events that altered practices in archives were those where records associated with previous régimes were relegated to archives to fulfill scholarly interests rather than the interests of the state administration. This occurred in the Netherlands in 1795 and in France after the French Revolution in 1799. Instead of being working documents, these records became historical curiosities, and archivists began to cater to historians rather than to government officials. Subject classification only worked, however, if one could assign a classification to every document. As long as archivists did not have to manage any records of the current administration, they were able to assign such classification. While it was possible for them to classify each and every document when the amounts were very small, however, as time went on inevitably more current records began to enter the archives and as the volume of records grew it was no longer

possible to treat records at the item level. The additional volumes began to affect the maintenance of a consistent classification scheme.

In addition to these reasons for abandoning subject classification for archival records, there was a growing realization that subject classification failed users in a number of important ways. For instance, subject classification physically assigned records to a single class. Further subject classification required a cross-reference system to be set up that linked the documents to other subjects, something that was extremely time-consuming for the significant amounts of individual documents that entered an archives. Yet records rarely provided information on only one or two topics, requiring a selection to be made as to which subjects were the most important. Organizing records classed by creator, however, gave unlimited points of entry, based on the activities and functions of that creator that could be captured globally for large numbers of documents tied together by their common provenance. Furthermore, there was a growing understanding that multiple relationships often existed between the records produced by one creator and that it was important to preserve these relationships. Later archival theorists would refer to this as the "organic" nature of records creation, reflecting the natural growth of records within a record-keeping system.

The French claim that they were responsible for reintroducing the notion of provenance when archivist, diplomatist, and historian Natalis de Wailly defined *respect des fonds* in a circular issued by the Minister of the Interior on April 24, 1841. In it, de Wailly stated that "all documents which come from a body, an establishment, a family, or individual form a *fonds*, and must be kept together." There is some debate about whether any consideration was given to original order. French archival theorist Michel Duchein maintained that *l'ordre primitif*, or original order, emerged shortly after de Wailly's original circular in France.^[10] Canadian archival studies student Alain Giroux argued strongly that de Wailly's circular implied that *respect des fonds* was only to supplement pertinence, or the organization of records by subject, not to replace it and that original order emerged in Germany. Giroux noted that Johannes Papritz's "Verwaltungsstrukturprinzip" was used to classify records below the *fonds* level, employing administrative units of an organization in order to classify its records.^[11]

In England, at about the same time de Wailly produced his circular in France, Sir Francis Palgrave, the first deputy keeper of public records, wrote in 1840 that archival records were to be placed in groups according to their provenance. Palgrave permitted a parallel "literary or theoretical classification" of records into subject groups to be registered on paper. This worthy attempt to establish the supremacy of *respect des fonds* was later supplanted by the physical rearrangement of records into different subjects or classes. In time however, Hilary Jenkinson,

archivist and later deputy keeper of the British Public Records Office from 1906 to 1954, returned to the notion of provenance. The first step the archivist would make, Jenkinson declared, would be to determine which creators created and accumulated the different records in the archives. This practice would have reflected Jenkinson's own experience where records were disassociated from their creators. Only the records of an administration "complete in itself, capable of dealing independently, without any added or external authority, with every side of any business which could normally be presented to it" would warrant being kept together and these would be called an "archive group."^[12] Once the creator was established, then the archivist was to study the history and organization of the administrations that produced the records, and to establish, or to reestablish as necessary, the original arrangement of the documents of the organization. However, as time went on and the volume of records increased, archivists abandoned Jenkinson's archive group and began to focus on the series or class level, a level that groups files or other physical units of related records together.^[13]

Although we do not know how the notions of *respect des fonds* and original order spread, a number of countries developed these ideas shortly after de Wailly's circular. In Belgium, an Order in Council issued by Louis Prosper Gachard dated December 17, 1851, regulated the State archives in the provinces with instructions similar to de Wailly's.^[14] In Italy, Francesco Bonaini developed the *metodo storico* in 1867, which included both *respect des fonds* and original order. This principle became state policy and was applied to all government records in Italy in 1875.^[15] In Germany, the director of the Privy State Archives, Heinrich von Sybel, issued regulations employing provenance or *Provenienzprinzip* written by Max Lehmann on July 1, 1881. This principle was augmented by the registry principle or original order.^[16] This principle made eminent sense in the context of the Prussian government because it was based on the central registry system used by the government bureaucracy. This system assigned designations to each document and then the designations were recorded in a central registry. It would have been exceedingly difficult for any archivist to try to tamper with such a rigid system once it was in place.

These developments, however, were eclipsed when the seminal *Handleiding voor het ordenen en beschrijven van archieven* or *Manual for the Arrangement and Description of Archives* by Dutch archivists Samuel Muller, Johan Feith, and Robert Fruin was published in the Netherlands in 1898.^[17] It is pretty certain that this manual, which championed provenance or *herkomstbeginsel*, was influenced by developments in Germany and France. All three writers referred in their text to German and French manuals on diplomatics and to various French and German writers. In addition, Muller attended several lectures at the Écoles des Chartes, the archival studies school in

France, in 1873. It is also quite clear from studies made of the private papers left by the three authors that provenance included both *respect des fonds* and original order.^[18] What made this development different from all the others across Europe was the influence the manual had on spreading and reinforcing these principles in other countries. The manual was published in German, Italian, French, and American editions in 1905, 1908, 1910, and 1940, respectively.

In their manual, Muller, Feith, and Fruin described the *fonds* or "archival collection" as "the whole of the written documents, drawings and printed matter, officially received or produced by an administrative body or one of its officials." Once the documents were placed in a repository, these collections were to be kept separate and in the same order that the organization that produced the records kept them in. The three authors felt that this order would correspond in the main to the organization of the administrative body.^[17]

In 1910, the Conference of Librarians and Archivists held in Brussels gave international recognition to the principle of provenance when conference attendees formally endorsed the principle. Interestingly, although the conference actually used the word provenance, none of the early archival theorists or archivists, including the French, used that word, but most often referred to some variation of *respect des fonds*. The word provenance does not come into common use in English-speaking countries until much later in the twentieth century. British archivist Hilary Jenkinson wrote *A Manual of Archive Administration Including the Problems of War Archives and Archives Making* in 1922 and Italian archivist Eugenio Casanova published *Archivistica* in 1928.^[19,20] These two manuals also helped publicize the ideas of *respect des fonds* and original order.

Waldo Gifford Leland, American historian and archivist, and New York State Archivist Arnold Johan Ferdinand Van Laer both attended the Congress in Brussels in 1910. Van Laer reported on the Brussels conference at a conference of archivists in Indianapolis in December of 1910, paving the way for the introduction of the principle of provenance to the United States. In a report to the Illinois State Education Building Commission in 1913, Leland outlined his understanding of the concept of provenance. He emphasized that the first activity of an archivist was to create a guide that outlined the various public offices and their functions. He felt that the records would clearly reflect the organization and functions that created them. These ideas were spread by annual meetings of the Public Archives Commission around the country. By the time the U.S. National Archives and Records Administration was founded in 1934, a number of state archivists were practicing the principle of provenance in their institutions.^[21]

The employment of the principle took a sudden turn in 1941 when the committee set up to study the adequacy of

finding aids at the National Archives introduced a variation of *respect des fonds*, which did not include original order and which established the “record group” as the unit of description. The record group was defined as “a major archival unit established somewhat arbitrarily with due regard for provenance and to the desirability of making the unit of convenient size and character for the work of arrangement and description and for the publication of inventories.”^[22] These record groups were themselves to be grouped into broad subject fields, such as defense or industry, or form, such as cartography or films, which it was hoped would aid in control. These groupings, however, were based in some cases on tenuous relationships, although the records continued to be identified by their creators. Commissions, for example, were all placed together even if they originated from different pieces of legislation to carry out completely different functions.

The reasons for the establishment of the record group were myriad. There were practical considerations to be made at the National Archives; archivists there had received 800,000 ft^[3] of records *in a single decade* and were looking at even faster and larger accumulations in the years to come. According to American archivist Frank B. Evans, the lack of a strong tradition in methodical record-keeping, the absence of a fully developed registry system, the fluidity of administrative organization, the relatively late establishment of a national archival agency, the institutional autonomy and procedural diversity encouraged by a federal system of government, the strong influences exerted by the allied professions of the librarian and the manuscript curator, and the lack of a stable terminology all contributed to the development of this unique definition.^[23] Whether the National Archives affected practices in other American archival repositories, or whether as American theorist Theodore Schellenberg supposed, the Library of Congress Manuscripts Division was responsible, Schellenberg discovered in 1942 that two-thirds of American repositories were arranging items chronologically and one-third were arranging material by subject, or using a combination of the two. In other words, almost no archives in the United States were employing the principle of provenance to arrange and describe their records.

Gradually, however, the ideas of *respect des fonds* and original order filtered down through the American archival community were strongly influenced by Schellenberg’s seminal text *Modern Archives: Principles and Techniques* published in 1956 and reinforced by his second work *The Management of Archives*, which followed in 1965.^[24,25] The archival community was also influenced by the writings of Schellenberg’s compatriot Margaret Cross Norton who, often quoting Jenkinson, maintained that provenance was made up of both *respect des fonds* and original order.

In Canada, archivists were introduced to European archival theory in the 1950s through their colleagues in the United States. The then Public Archives of Canada

followed the example of what became the National Archives and Records Administration by implementing a similar variation of provenance. In 1966, W. K. Lamb wrote in the journal *American Archivist* that the Public Archives of Canada used the word manuscripts to describe private papers and that this term enabled the archives to “organize the vast mass of miscellaneous papers into manuscript groups, each of which brings together collections that are alike in kind or in period or, occasionally, in subject matter.”^[26] The first Canadian essay on the principle of provenance was written by Robert Garon in Québec in 1969. However, it was not until 1977 that the attention of Québec archivists was drawn to the concept of *respect des fonds* by an article by French archivist Michel Duchéin.^[27,28] By the mid-1970s, Anglo-Canadian archivist Carl Vincent began to speak of using provenance theoretically on paper to define the record group, divorcing it from physical arrangement.^[29]

The Consultative Group on Canadian Archives’ report, published in 1980, established that archivists should employ the principle of provenance in order to provide the context of records. The group added what it called an extension of the principle that would become the first in a series of extensions of the concept. This extension was the principle of territoriality, which maintained that the locale or milieu of the records was part of their context. Allied to the principle of provenance was the principle of unbroken custody that stated that there needed to be a chain of continuous custody of the records in order to ensure their integrity. Thus, the group felt that archival materials “should be kept together, passed through as few hands as possible (at every stage with proper authority and continuity), and remain as close to their source as possible.”^[30] This report would be the foundation of the Bureau of Canadian Archivists’ Planning Committee on Archival Descriptive Standards that chose the *fonds* as the basis of archival description in 1992. Finally, the translation of Michel Duchéin’s article into English in 1983 helped galvanize English-speaking archivists in Canada to apply the principle of provenance in their institutions.^[1]

Australian archives employed provenance but in 1964 abandoned the record group in favor of the series. Peter J. Scott, an archivist at the National Archives of Australia, published an article in *The American Archivist* in 1966 that suggested that the record group was not capable of reflecting the variety of relationships that existed between records and government agencies. The lower level of the series was the only level that would allow records to be properly linked to all the various agencies that might have had responsibility for producing the records. As departments changed, as the names of departments changed, as their functions changed, as responsibilities for functions were split between departments, the records that arose from the same functions would be linked together. Peter Scott was the first to seriously challenge the level at which description would occur. After he fired the opening salvo

in the battle over the level of the provenancial unit, there was a brief flurry of articles either supporting him and/or championing the status quo. Since Scott's application of provenance at the series level did not fit the records of private individuals very well, where series were ill defined and inconsistent, his system did not spread very far outside government archives in Australia. Several writers, including Australian Chris Hurley and Canadian Terry Cook, later noted that the real advancement that Scott made was not just linking records to multiple creators but more importantly breaking archival description away from the physical nature of the records. Scott in effect separated the description of the creator from the description of the records.^[31]

HISTORIC DEVELOPMENTS IN THE MEANING OF PROVENANCE

While the definition of provenance, or what it was, changed over time, the meaning of the principle of provenance, or what it meant for archival practice, also changed. In Hilary Jenkinson's manual, for instance, he stated that papers that did not have the context provided by provenance would lack the qualities of *authenticity* and *impartiality*. Authenticity meant that the records were free from the suspicion of tampering; they were an authentic record of the person or organization that created them. Impartiality referred to the fact that records, by being drawn up in the course of daily activity, were an impartial testimony to the actions they represented. This was a very important point for Jenkinson. Archival records were not drawn up in the interests of posterity.

In the United States, Margaret Cross Norton felt that records were evidence and needed to be proven as authentic in order to be employed in a court of law and provenance was the tool to accomplish this. Theodore Schellenberg also saw records as evidence but, like Jenkinson, felt that they were evidence of actions. A birth certificate, for example, was the evidence of a government recognizing and documenting a birth; a diary was the evidence of persons recording their thoughts. This was the records' *evidential* value. But beyond the evidential value of records, Schellenberg felt that the contents of the records also held value and this was the records' *informational* value.

Based on the qualities of evidential and informational value, Schellenberg identified two uses for records. The *primary* use of a record was its usefulness to its creator. The *secondary* use of a record was its use to persons other than the creator. Schellenberg felt that records needed to be preserved for reasons beyond the creator's benefit in order to be considered archives, although the records might well be used by both the creator and others. Schellenberg felt that certain records would be preserved for their informational value only and not for their evidential value, and so records kept for that purpose could be

reorganized in an order that would best serve the needs of both scholars and government officials. Thus in that case, archivists would maintain the records by their creator but would not maintain original order.

French theorist Michel Duchein stressed the context of provenance, or the who, what, when, where, and why of records creation. He also talked about how to determine exactly what a *fonds* was, particularly the level of records creation. His *maximalist* level assigned the *fonds* at the highest level. Duchein pointed to Russia which treated the entire Russian country as forming a single *fonds*. Duchein's *minimalist* level would treat a department of a government as a *fonds*. When determining a *fonds*, the archivist would need to consider many qualities of the creator, such as a body having legal status, a structured, known organization regulated by an organizational chart, and so on. The *fonds* would be the basis for description.

Adolf Brenneke, the Director of the Prussian Privy Archives in Berlin, introduced in his lectures in the 1920s and 1930s the notion that provenance should reveal the functions of a business or government. It was the duty of the archivist to organize records to reflect how they were created. Researchers, he said, needed to know the structure of an organization, the organization's tasks and functions, and the structure of the records.^[32] Brenneke was farsighted; many modern archivists have returned to this need for functional analysis of an organization either to produce a description of the record-keeping system or to appraise the value of records arising from these functions.

Thus, from the early archival theorists we can understand that keeping records by creator ensures that one can judge the authenticity of the record by answering such questions as who created these records for what purpose? In other words, are these documents what they purport to be? The context of the creation, under what conditions these records were created, is also critical to determining the value and reliability of the contents of the document. This becomes essential when one is caring for documents that ensure the rights of citizens for example. The legal values of records must be maintained in such cases. To use a modern-day example, knowing that a governmental office of vital statistics has recorded a death ensures that a will can be probated and heirs can inherit. By keeping records in their original order, where there is one, the archivist ensures that the functioning of the individual or organization is captured.

MODERN THINKING ABOUT PROVENANCE

In the early 1980s, there came a sea change in the understanding of provenance, propelled in part by both the urgent demand of electronic records and the possibilities offered by computer retrieval systems. In the United States, Richard Lytle reported on an experiment he conducted in comparing the results when archivists used

provenance to retrieve archival materials versus when a computer system used content indexing methods of subject retrieval. He found that both methods had fairly similar retrieval results, but that provenance had its own strengths and could be improved.^[33] In Canada, Gordon Dodds, addressing members of the Association of Canadian Archivists at their annual conference in 1982, entreated delegates to study provenance as a tool to tackle modern archival problems. His call to action was answered shortly after in an article by Terry Cook, who stated that archivists needed to shift from providing information from records to providing a contextual understanding of the provenance of the records.^[34,35]

In the Winter 1985–1986 issue of *Archivaria*, Americans David Bearman and Richard Lytle wrote a prescient article that both consolidated thinking presented by earlier thinkers such as Scott and foreshadowed many later developments surrounding provenance. The two authors stated that archivists could make a unique contribution to information management by providing provenancial information about how organizations create, use, and discard information; provenance information about organizations (or creators) should be separate from descriptive data about the records themselves; archivists needed to capture organizational relationships in their provenance information; many-to-many relationships between creators and records also needed to be described; archivists should focus on the functions of organizations and the forms of their records to enhance the provenancial record; the authority record should include information about the history, structures, relationships, processes, and activities of records creating organizations; and such a record could show changes in particular functions or activities over time. Bearman and Lytle saw all of this enhanced provenancial information as providing a solid foundation for improved archival retrieval systems.^[36] These first articles, combined with critical writings by Canadian Hugh Taylor a few years later, were the beginnings of a flowering of the notion of provenance.^[37,38]

One of the new questions being asked was would provenance apply equally to both the physical and theoretical aspects of records? Although most assured the principle of provenance was meant to apply to the physical arrangement of archives in the repositories of the late eighteenth and nineteenth centuries, that slowly changed over time once more recent records began to enter archives. The volumes of these recently created archives increased exponentially, and many of the accumulated records remained open for further accruals. Archivists were no longer able to physically group together the total archival records of defunct administrations. Records typically began to be received and processed by archives in varying amounts referred to as accessions. Although there were still attempts at some sort of physical organization of records as late as the 1970s, eventually records were placed on shelves as they were received in whatever way made most

efficient use of space or eased retrieval and were assigned control numbers. There was no attempt to keep the records of a single department or person physically together. Archivists acknowledged that these accessions had to be maintained in order to preserve good physical and administrative control over the records. The accession would tell when the records were acquired, from whom and under what conditions. Archivists no longer used provenance in order to organize records physically in the archives but theoretically on paper.

With the advent of electronic records, the question was would provenance apply to such records, which often remained in situ, where they were created? The answer to the question of the application of provenance was fairly straightforward. As Terry Cook stated, “a world of relational databases, of complex software linkages, of electronic office systems, of hypermedia documents, of multilayered geographical information systems, is, when all the high-technology rhetoric is put aside, still a world of information relationships, of interconnections, of context, of evidence, of provenance.”^[39] Whether the records remained with the creator or were transferred into the archives, it would still be critical to know who was responsible for the creation of the records and the context of that creation and thus provenance would still be critically important to capture. Canadian Luciana Duranti emphasized that among other aspects, “an authentic electronic record is one the identity and integrity of which can be verified, that is, a record whose provenance and authorship are known at every time.”^[40]

At about the same time as Bearman and Lytle were writing of provenance in *Archivaria*, American Max Evans proposed the creation of authority control, or officially separating creator histories and linking them with all records associated with that body, which created a new relationship between provenance and original order.^[41] Canadian Debra Barr expanded on Evans’ idea, noting that inventories should demonstrate connections of records to as many creators *and other records* as was appropriate.^[42,43] Chris Hurley added to this notion by suggesting that the context of records creation should expose multiple relationships based on formal functions.^[44] Since then there has been major work on descriptive standards that would allow this separation of provenancial information from the descriptions of records, including the creation of the International Standard Archival Authority Record (Corporate Bodies, Persons, Families) or ISAAR (CPF). Australian Adrian Cunningham noted that the second iteration of ISAAR (CPF) added a new element to provenancial description: the relationships between creators and records. Michelle Light emphasized the importance of including all names or terms representing an entity as it changed over time.^[45,46] David Bearman’s desire to have functions recognized in provenancial descriptions came about with the development in 2007 of the ICA’s International Standard For

Describing Functions, which provided guidance for describing the functions of corporate bodies associated with the creation and maintenance of archives, although the standard separates the description of functions from the description of provenance.^[47]

Beyond these new considerations and developments, there has been a virtual explosion of writing on the subject, including proposals to radically expand the very notion of what constitutes provenance. Many of the authors have built on aspects of each other's work, adding new concepts and ideas. In analyzing provenance from a postmodern perspective, Terry Cook proposed a societal provenance that would acknowledge that records are authored and interpreted in a social context. This notion was seconded by Tom Nesmith who said this expanded view of provenance would contextualize the records more fully by providing information about the social circumstances that surrounded their creation. In this way, the provenance can never be fully known but is constantly emerging and evolving.^[48,49] American Jeannette Bastian felt that creators of records and their acts of creation were tied to the actual spaces in which they engaged. This "provenance as place" suggested that there were multiple levels of provenance.^[50] Lori Podolsky Nordland encouraged archivists to go beyond the surface interpretation of records to do the research and deconstruction of the records if necessary to add a "secondary provenance" to their description. She also noted that as records underwent what Hugh Taylor referred to as a "transmedia shift," the provenance of the record shifted or acquired new layers of meaning.^[51] Joel Wurl proposed ethnicity as a form of archival provenance. This understanding of provenance would lead archivists to overcome a tendency toward excessive veneration in documenting ethnic groups, avoid oversimplified notions of cultural diversity, and would lead to the stewardship, instead of custodianship, of the records of ethnic communities. Chris Hurley stated that the provenancial context beyond that of the immediate creator should also be captured.^[52,53] Emily Monks-Leeson also extended the coverage of provenance to new contexts created by new uses. "...As records take on new meetings and new contexts, understandings of provenance can shift to encompass not only the original contexts of creation (which should be preserved), but also those new contexts in which records come to belong."^[54]

Other authors such as Canadian Laura Millar noted that while provenance was originally based on the concept of the *fonds*, the archival notion of the *fonds* was simply a theoretical construct. What came to the archives could never be the whole of the records created and accumulated by the creator, and what was preserved by the archives became an even smaller subset of the whole.^[55] In Britain, Geoffrey Yeo agreed that the term *fonds* rarely describes the whole of the records of a single creator and furthermore, when those records are spread across a number of institutions, for each of those institutions to designate their

part of a larger aggregation as a *fonds* is "misleading, if not erroneous."^[56]

In applying provenance to personal records, Geoffrey Yeo said that conventional approaches to archival description used in capturing provenance did not do justice to the often complex histories of personal archives. Chris Hurley in Australia noted that all organizational records have both corporate and personal provenance.^[56,57]

Laura Millar in recent years has suggested that provenance needs to capture three separate components: the creator context, the record-keeping context, and the custodial context. She based her definition of *creator context* on the definition by Terry Cook, stating that archivists should capture the functions and activities of the creator that produced the records. The *records-keeping context* would record the physical management and movement of the records over time and answer such questions as how the records were created and used, where the records moved to and why, and whether any records were lost, destroyed, enhanced, or altered and why, among others. The *custodial context* would document how the records came to be in the archives and how the archives managed the records over time.^[55]

In terms of applying the principle of provenance to various archival functions, for Terry Cook, provenance was a tool for the appraisal of records, particularly the vast amounts of case files and records generated by government. Many other authors have agreed.^[58] As for the role of the archivist in the principle of provenance, Emily Monks-Leeson in 2011 wrote that archivists and archival institutions contributed to the provenance of the records "through their acts of interpretation and inscription," and thus this also needed to be part of the description. Tom Nesmith noted "in their daily work archivists... make decisions about the origins of a record. For whatever reason, they focus on certain aspects of it which seem meaningful to them and omit much else which may or may not be knowable." He suggested that archivists may want to highlight different aspects of provenance depending on the records.^[54,59] And finally, according to Jennifer Meehan in the United States, archivists should include information about their own maintenance, transmittal, and use of the records by all custodians, themselves included.^[60]

Finally, regarding original order, in the Netherlands, Peter Horsman proposed in 2002 the principle of (virtual) provenance that would be a visualization through archival narratives that would describe "functional structures, both internal and external." Tom Nesmith stated that archivists should speak of the order the records are in when they arrive at an archives instead of original order.^[61,62] As other postmodern archival scholars recognized, Canadian Heather MacNeil noted that the original order of a *fonds* is constructed, not found, by the archivist. She stated that "the arrangement of a body of records is not fixed at a single point in time. The survival and ongoing preservation of the records mean that they are in a continuous state of becoming as their physical and intellectual orders are shaped and

reshaped, contextualized and recontextualized, initially by their creators and subsequently by their custodians.” Archivists did not restore original order so much as construct and reconstruct it in accordance with their own biases and understandings. And finally, while archivists might understand the functions that created the records, they were also reminded that those records no longer carry out those functions. MacNeil called this “archivalterity.”^[63] When applying original order to personal records, Jennifer Meehan maintained that archivists could not use approaches that worked with organizational records but needed to focus attention on the relationships between records and activities whether there was a discernible order or not. Archivists should concentrate on the relationships between records and the activities that gave rise to them.^[60]

CONCLUSION

The original conception of provenance was that it was the origin of archival records, and the notion that records of one creator must not be intermingled with those of another was the foundation of the principle of provenance. The corollary of this principle was the concept of original order that not only must records be identified by the person or organization that created or accumulated the records, but also the records should remain in the order in which they were originally kept. These two principles were born of necessity as European archivists struggled to gain physical control over records that had been passed from administration to administration. Depending on the unique situations of each country, different adaptations and interpretations of the concepts developed as they spread from Europe to other parts of the world. It is difficult to say whether countries outside the western tradition independently arrived at a similar principle (as only a small amount of archival literature from Asia, South America, the Middle East, etc., has been translated into English); this warrants further investigation.

Closely tied to this however has been the major struggle to identify the provenancial unit of control that formed the basis for arrangement, description, reference service, and so on. One could not identify the provenance of records unless one were able to determine the unit to which the identification would be attached. The advent of computers and the development of descriptive standards to take advantage of computer power only exacerbated the problem. Archivists began to take a renewed interest in provenance and original order and question the identification of the unit, the *fonds*, the archive group, the record group, or the series. It was only a matter of time before they began to reconsider every aspect of provenance and original order and their meaning for both archivists and researchers. Today the idea that provenance is simply the origin of archival records has been transformed into the idea that provenance captures the entire context of

the creation of records, everything from the identity of the person, persons, or organizations that created them, the system that supported them, and the conditions under which the records were created, to their movement from originator to archives, and the archivist or archivists who appraised chose and described them.

The principle of original order likewise changed to accommodate the postmodern realities that original order does not exist independent of the person who is describing it, and that it should reflect the relationships that exist between creators and records.

No doubt the future will bring further developments in thinking about the principles of provenance and original order. The changes these theoretical proposals have made to actual practice have been slow however, tempered by the awful reality of enormous twentieth-century backlogs of unprocessed records awaiting arrangement and description and the looming volume of physical records created from the Second World War on beginning to show up on archives' doors. A breakthrough that brings theory and practice together will require new thinking that concentrates on application.

Provenance of Museum Objects

Layna White

San Francisco Museum of Modern Art, San Francisco, California, U.S.A.

Abstract

Museum professionals, museum supporters, and observers understand provenance to be the history and circumstances of an object's ownership and possession. Knowing the story of an object's ownership and possession may contribute to understanding the relative meanings and significances of that object to individuals, nations, groups, and locations and may improve understandings of legal rights, titles, and interests in objects. Museum professionals understand that ascertaining and sharing provenance information can further public trust and public service and build historical records for objects. However, the ability of museums of any type to ascertain provenance for objects is greatly dependent on the motivations and practices of past owners or possessors, and other interested parties, to document and share knowledge about ownership and possession. Discussions and actions within the last several years related to the history and practices surrounding twentieth- and twenty-first-century acquisitions of certain objects by museums have focused acute attention on the importance of studying, documenting, and revealing provenance.

INTRODUCTION

The meaning of provenance in a museum context is unambiguous. Museum professionals, museum supporters, and observers understand provenance to be the history and circumstances of an object's ownership or possession. While the definition of provenance may be commonly understood, the ability of museums of any type to ascertain provenance for objects is greatly dependent on the motivations and practices of past owners or possessors, and other interested parties, to document and share knowledge about ownership and possession.

Expressed stewardship mandates of museums commonly imply aspects of collecting, preserving, interpreting, and exhibiting objects. In museum parlance, *object* is used to describe very generically the fullest range of items conceivably collected, preserved, interpreted, and exhibited by museums, recognizing the flattening effect of using one term to denote items of potentially vastly different types and meanings, ranging, for instance, from works of fine art such as paintings and sculptures, and artifacts such as flags and masks to natural world specimens such as plants and shells. Distinctions might be drawn between definitions of *object* used here as a generic, equalizing term to describe products of humankind and nature, and *cultural property* used elsewhere to identify products of humankind and nature deemed by some to have special significance to the cultural heritage of a nation or group, or special significance to a location. This entry intends to review, under one umbrella, the meanings, roles, and practices around provenance information within the context of diverse types of museums, such as public, private, and governmental museums of art, cultural history, history, anthropology, natural history, and science.

The following provides an overview of topical issues facing museum professionals when studying, documenting, and sharing information about provenance, beginning with a general discussion of ownership and possession, and the relevance of such to museum policies, particularly reflecting on recent interest in the history and practices surrounding twentieth- and twenty-first-century acquisitions by museums of certain types of objects. The entry then considers sources for provenance information and explores the challenges of finding partial, conflicting, or otherwise not wholly complete and accurate information for an object, and the part museums may play in perpetuating the availability of only partial information.

While provenance research, documentation, and dissemination competes with other demands for museum resources, museum professionals understand that work around ascertaining and sharing provenance information can further public trust and public service and build historical records for objects. Within at least the last 40 years, motivations from within museums, and influences from without, have kept discussions of provenance related to museum objects active and passionate.

CUSTODIAL PATHS

The ownership and possession of an object is marked chiefly by place (location), time (duration), and purpose (circumstance). To determine and, ideally, ultimately, to share an object's provenance, museums must first map the path of ownership or possession, from the place and time of an object's origin through a maker, patron, or culture or from the time of an object's discovery at a findspot, through any subsequent points of rest and transactions,

reaching the place and time of that same object's current or last known owner or possessor. The term *provenience* is used by archeologists to mean the original context of an object or, more precisely, to mean documentation of an object's original findspot, including description of its placement and interpretation of its situation relative to other objects found in the same place. This entry considers the findspot for an archeological object to be the starting point of its custodial path.

Custodial paths—marking points of rest and transactions—can vary in duration, purpose, and traceability, with some objects changing hands more frequently and more transparently than others. Objects might change hands through transfers of title, such as by gift, bequest, purchase, sale, or exchange. Ownership and possession might otherwise be defined by agreements for commissions, shared ownership, restitution, or repatriation. In theory (although unlikely in practice), an object might be transferred from the original owner, or location, through a hybrid and abbreviated combination of private, unknown, corporate, governmental, and museum collections, with the majority of transfers in ownership occurring at the private collection level (p. 269).^[1] With familiar or longer-established media—such as paintings, decorative arts, coins—in layman's terms, owning an object is equated with having physical control of the object as property. Some contemporary artists are pressing understandings of what it means to own an object in that, in some cases, the original work of art may not have a primary, staid physicality. Observations about works created by the artist Tino Sehgal (born 1976, London; active Berlin) provide just one example:

Art can be defined, provocatively, as an intangible quantity that transforms an ordinary object—a urinal, a soup can, an unmade bed—into something worth many times more than its material value. Tino Sehgal seeks to isolate precisely that intangible quantity. His art is completely immaterial; it can be bought and sold without involving any objects whatsoever.^[2]

In such cases, an owner may acquire from the artist a right to make new instances of the artist's original concept based on parameters agreed upon by the artist and the owner. Exercising a right to make new instances may or may not yield a physical object, and the outcome may vary, instance to instance, prompting questions about the object per se and what is actually being collected.

In other cases, simply possessing a physical object may not constitute legal or valid right, title, or interest in that object, as when, for example, a current owner consigns an object to an auction house in order for the auction house to promote the object, its maker, or past owner (e.g., someone of renown) when brokering the sale of that object to a new owner, or when authorities in a country at war give temporary custody of at-risk objects to a public museum located elsewhere for safekeeping until the objects can be returned to the country of origin. Provenance

information for an object should distinguish between those who have owned an object and those who have held the object transitionally.

Tracing the custodial path for an object is also intertwined with verifying that the information at hand about an object, its path, and caretakers is connected with the actual object under review. The concerns here include receipt of completely fabricated provenances or innocently inaccurate mix-ups that connect otherwise reliable details about provenance to the wrong object. Demonstrating verisimilitude between provenance information and an actual, or the original, object through place and time, however, might be predictably and acceptably variable. As noted, with some contemporary works of art, for example, a collector may acquire a right to use the artist's original concept, and any "object" resulting from exercising that right may or may not be the same as any previous instance. This kind of predictable, intended variability is distinguished from circumstances where caretakers take it upon themselves to change an object in ways unexpected and unintended by the artist/maker or culture, as when, for example, a medieval altarpiece has been radically restructured by division into parts for dispersal to different locations.

Rightful, Clear, or Good Title

Knowing the story of an object's custodial path may contribute to understanding the relative meanings and significances of that object to individuals, nations, groups, and locations, and the object's function within any intended and subsequent contexts. From legal and ethical perspectives, knowledge of provenance may improve understandings of rights, titles, and interests in objects. Ownership may be described as rightful, legitimate, legal, valid, clear, clean, good, and proper as in, having rightful, clear, or good title in objects. The means and requirements for acquiring rightful, clear, or good title in an object may differ under different nations' laws and may vary by type of object (e.g., requirements for acquiring a well-documented modern sculpture directly from the artist may be different from the level of diligence expected when acquiring a fragment of an ancient urn long removed from an archeological site).^[3–5]

Depending on the types of objects and scopes of collections involved, the museum professional researching provenance will be aware that countries such as China, Egypt, Greece, Peru, and Turkey have modern patrimony laws that give the national government primary ownership rights and interests in some objects created or newly discovered in that nation's territories. Patrimony laws imply support for cultural nationalism, or a national cultural heritage view, which recognizes that certain objects have special significances to originating nations, groups, or locations, and privileges a nation's rights to possess and provide access to those objects over other ownership

interests, in some cases, regardless of the perceived legitimacy of subsequent transfers in title or possession.^[6] This position has been criticized as being retentionist and politically based.

The museum professional researching provenance will also be aware that some nations—including Australia, Canada, and the United States—have laws covering the possession and control of human remains and certain cultural materials. For example, the U.S. Native American Graves Protection and Repatriation Act of 1990 (<http://www.nps.gov/nagpra>) recognizes that descendants have primary rights to possess, control, and guide outcomes of ancestral remains, funerary and sacred objects, and cultural patrimony notwithstanding current possessions by nondescendants.^[7,8]

Some museum professionals, museum supporters, and observers advocate cultural internationalism, or a world cultural heritage view, emphasizing the value of more open access to objects in furthering understandings of cultural heritage. Cultural internationalism holds that objects are common patrimony, belonging to all peoples, and assumes museums—depending on type, mission, and scope—need objects to move from location to location in order for museums to collect, preserve, interpret, and exhibit objects. This view foregrounds a belief in the contemporary museum as an impartial caretaker in providing objects, regardless of origin, with a good home, good care (such as curatorial, documentation, and conservation services), and good visibility through public display and discourse, an assertion reproached by others as elitist and encouraging destruction of original context.^[9–11]

The “Elgin Marbles” (or the Parthenon sculptures) at the British Museum in London are a frequently cited example of a dispute over ownership, possession, and location.^[6,12,13] In brief, the “Elgin Marbles” comprise a group of sculptures removed from the Parthenon on the Acropolis in Athens between 1801 and 1805 under the direction of Lord Elgin (an early-nineteenth-century British ambassador to the Ottoman Empire), with the assent of Ottoman Empire officials (then in control of Greece). Elgin transported the sculptures out of Greece to Britain; and in 1816 the sculptures were acquired by the UK Parliament from Elgin, and placed subsequently in the British Museum (https://www.britishmuseum.org/about_us/news_and_press/statements/parthenon_sculptures.aspx).

Some have argued that the “Elgin Marbles” in the British Museum should be returned to Greece because the sculptures are intrinsically Greek, therefore of utmost significance to Greece and the identity of the Greek people; this perhaps in addition to believing that the removal of the sculptures by Elgin was legally and ethically problematic. Taking this view, the sculptures should be returned and installed in the Acropolis Museum in Athens, opened in 2009 and located very near the Parthenon, providing an obvious place and time to reunite the sculptures removed

under Elgin’s direction with those objects from the Parthenon still remaining in Athens. Counterarguments for keeping the sculptures at the British Museum consist of the perceived legitimacy of the transactions (to Elgin from Ottoman officials; to Britain by Elgin), as well as the bond the British people now have with the sculptures, and beliefs that the British Museum will continue to provide the sculptures with a good home, good care, and good visibility.

When questions about ownership or possession arise, an object’s documented provenance may provide examiners and owners with key information. A previous owner may seek to recover an object when the modes of transfer surrounding later possessions are deemed problematic, a determination perhaps made partly after considering information (or lack thereof) about an object’s path of ownership, possession, and location.^[14] In some cases, the provenance secured by a current owner may be considered irrelevant when weighed alongside assertions that, for example, a nation holds primary rights to an object. Here, calls to right wrongful possessions may point to the special cultural, historical, archeological, religious, or spiritual significance of the physical object to a nation, group, or location (an argument put forth by both parties in the case of the “Elgin Marbles”).

Interest in Provenance

Within at least the last 40 years [loosely marked by the 1970 United Nations Educational, Scientific and Cultural Organization (UNESCO) Convention described in the following text], governments, journalists, merchants (such as dealers and auction houses), and communities of museums, researchers, and descendants of object makers have focused acute attention on the importance of studying and revealing provenance. Much attention has been given to revealing information about aspects of ownership or possession that might suggest questionable transfers or, conversely, might provide evidence or convincing arguments to quash such suggestions. Discussions and actions are particularly heated around identifying and possibly returning to previous or rightful owners objects looted, seized, and/or illegally exported in the twentieth and twenty-first centuries such as antiquities, archaeological objects, and ethnographic materials taken clandestinely by individuals from historical structures and archeological sites located around the world and works of art and Judaica abandoned unwillingly by owners or taken forcefully in Europe during the Nazi era. DeAngelis poses the question, “. . .when can we ignore misdeeds of the past?” (p. 253);^[15] see also Merryman^[9] and Yeide et al.^[16] for descriptions of pre-twentieth-century plundered objects finding their way into museum collections.

Museum organizations and international bodies such as the American Alliance of Museums (AAM, formerly the American Association of Museums), the Museums

Association in the United Kingdom, and UNESCO have campaigned to encourage museums to document and share, as widely as possible, images and descriptive information about objects in permanent collections, including information about known and incompletely known provenance. Calls for information sharing and transparency related to collecting activities often point to the public service and education goals of museums as reasons enough to make information about objects available through, for example, online collections catalogs, print publications, and on-site exhibitions.

MUSEUM POLICIES

Each type of museum may face, and certain objects may pose, distinct challenges relating to provenance. All museums, however, may consider a set of fundamental questions relating to ownership and possession when, for example, publishing descriptions of objects in collection or exhibition catalogs and borrowing objects from other collections for inclusion in temporary exhibitions. Questions about ownership and possession specifically comprise part of the diligence and care exercised by museums today when accepting or buying newly proposed objects for permanent collections.^[17,18] Fundamental questions are considered concerning where an object has been, with whom, when, and under what circumstances. Contemporary museum policies for acquiring, preserving, interpreting, and exhibiting objects may acknowledge the importance of ascertaining as complete and accurate provenance information as possible in furtherance of good stewardship of objects (acquired for permanent collections or borrowed for temporary exhibitions), building historical records for objects, and sustaining public trust by demonstrating ethical practices.

It is not unusual, however, for museums to know imperfectly, at present, the full story of an object's ownership and possession, from place and time of origin to the current or last known owner or possessor. Museums will need and want to continue operating in the time between having partial, more than partial, and perhaps complete knowledge of provenance. In support of collecting activities in particular, a museum may establish parameters for accepting, buying, or rejecting proposed objects when provenance is, at the time of offer, known incompletely. For instance, a museum's acquisition policy might place the responsibility of judging and advocating the acquisition of objects with limitedly known, but not suspicious, provenances squarely in the hands of museum curators. See, for example, the British Museum's *Policy on Acquisitions*.^[19]

Some believe, and museum acquisition policies may imply, that museums should be in positions to provide objects with good homes, good care, and good visibility. In other words, assuming objects are acquired properly and through open channels (e.g., reputable commercial

markets), and absent evidence of problematic transfers, museums are in better positions than some to be repositories and advocates for objects with incompletely known provenances.^[20] While a currently incompletely known provenance does not automatically or necessarily mean that something about an object's history of possession is problematic, others argue that by continuing to acquire objects (particularly those originating from historical structures and archeological sites) with incompletely known provenances, even good-faith donees or purchasers (who have conducted some form of due diligence and acquired objects properly), might inadvertently intensify the market for objects with problematic histories of possession and, further, encourage contemporary clandestine stripping of objects from historical structures and archeological sites, without regard to documentation or interpretation, resulting in loss of knowledge about contexts and meanings relative to a place, time, and people.^[21]

The international agreement, the 1970 UNESCO Convention on the Means of Prohibiting and Preventing the Illicit Import, Export and Transfer of Ownership of Cultural Property (<http://www.unesco.org>), intends to protect objects from illicit removals and changes in possession, and protect nations from undue loss of cultural heritage. Many museum professionals, museum supporters, and observers have generally interpreted the principles and directives articulated in the Convention to mean that, to be acquired soundly and ethically today, certain types of objects must have been in proper circulation outside an originating nation before 1970 (using the date of the Convention as a marker), or have been legally exported from that nation and in proper circulation after 1970. Contemporary museum policies may refer to the Convention as one benchmark to apply when assessing the soundness of acquiring certain types of objects.^[22,23] The literature includes passionate discussions about the implications of contemporary exporting and importing of objects, such as antiquities and ethnographic materials, with currently incompletely known ownership histories. It is generally agreed, however, that preventing illicit removals of objects from structures and sites should be a priority for the cultural heritage community.

MUSEUM PRACTICES

Beginning in the 1990s, many museums began making mostly modest portions of collections information available on institutional websites, including, to greater and lesser extents, some provenance information about objects. Ongoing moves by museums to share more collections information on websites, other digital platforms, and through linked open-data initiatives are in line with expectations of museum professionals, museum supporters, and observers that museums should share what

they know or believe about artists/makers, the objects themselves, and the values, meanings, or functions associated with objects, and encourage discourse with museum audiences about objects and these contexts.

In this respect, provenance is one among several areas of interest in museums competing for research, documentation, and dissemination resources. Museums may need to prioritize which objects in a collection and which types of information will be the focus of research, documentation, and dissemination at a given time. Retrospective provenance research may be higher or lower in priority depending on the museum and its influences, such as the expressed interests of museum supporters (including museum audiences) and museum observers (including museum professional organizations and government agencies), as well as by work underway for contemporaneous museum activities (e.g., inventorying collections, making new acquisitions, exhibitions, publications, and conserving objects). Permanent professional positions focused solely on provenance research are uncommon in museums, excepting perhaps specialized positions created by some larger museums to speed sharing of provenance information. Provenance research is more likely part of a defined project, or folded into the routine information activities of staff with curatorial, registrarial, or documentation responsibilities.

Efforts to address issues related to some twentieth- and twenty-first-century acquisitions of antiquities, archeological objects, and ethnographic materials and looting of objects by the Nazis provide examples of expressed interests influencing museum prioritizations for research, documentation, and sharing of provenance. As a case in point, in 2000 the AAM, Association of Art Museum Directors, and the Presidential Advisory Commission on Holocaust Assets announced an agreement recognizing the commitment of U.S. museums to disclosing provenances for objects in permanent collections that might have changed hands in Europe during the Nazi Era (1933–1945).^[24] In 2006 the Conference on Jewish Material Claims Against Germany sharply criticized U.S. museums for their slowness in making available provenance information for objects in accordance with the 2000 trilateral agreement. Today, the responsiveness and actions of U.S. and European museums in addressing matters of provenance for objects within this scope continue to garner international attention and concern.^[25,26]

Museum Standards

Museums demonstrate differing practices for and commitments to sharing provenance information for all types of objects. Some museums may make available only the known and verified provenance for an object, which might include vague references to past owners (e.g., gift of an anonymous donor) and might exclude information for all but the most immediate past owner (i.e., excluding owners prior to the anonymous donor), and/or skim over known

gaps in the history of ownership or possession. Other museums may communicate, bluntly, in widely available online records that there are known gaps in the custodial path for a particular object. See, for example, efforts of U.K. museums to share information about objects with gaps in provenances covering the Nazi era: <http://www.collectionstrust.org.uk/collections-link/cultural-property-advice/spoliation>. For a chair made in France in 1925, for example, a museum might note that before acquisition by the museum in 2007, the chair was in the private collection of Jane and John Doe from 1940 to 2007, but the location of the chair from 1925–1939 is unknown. Putting consistently described provenance information in a shared online environment may increase access to that information, and help bring together distributed, related content, but its usefulness—to museum professionals, museum supporters and observers, previous owners, and descendants of object makers—will depend in some measure on the completeness, accuracy, and understandability of the information. For instance, the museum data standard Categories for the Description of Works of Art notes, “It should be possible, for example, to locate all the works in a particular collection, or to answer questions such as ‘What works, now in American collections, were owned by the eighteenth-century Venetian collector Padre Resta?’”^[27]

Museums keep provenance information, particularly about objects in permanent collections, in a combination of internal systems typically comprising a collections management system and documents (paper or digital) authored or collected by staff with curatorial, registrarial, or documentation responsibilities. Standards for museum object information reflect practices and certain expectations around provenance documentation and dissemination. A museum might refer to standards such as the Categories for the Description of Works of Art (CDWA) (http://www.getty.edu/research/publications/electronic_publications/cdwa/index.html), CIDOC Conceptual Resource Model (CIDOC CRM) (<http://www.cidoc-crm.org/Version/version-6.2>), and Spectrum (<http://www.collectionstrust.org.uk/spectrum>) when planning or vetting current systems for documentation. Each of these standards refers to ownership and possession, and each might offer museum professionals’ part, or most, of what is needed to organize provenance information in, for example, a collections management system.

For example, the CDWA includes several data elements related to provenance:

- Ownership/collecting history—provenance description (e.g., prose description of the custodial path)
- Ownership/collecting history—owner/agent (e.g., Doe, Jane)
- Ownership/collecting history—transfer mode (e.g., gift, purchase)
- Ownership/collecting history—owner’s credit line (e.g., Gift of Jane and John Doe)

- Current location—repository/geographic location—(e.g., City Art Museum, My Town)

The CDWA identifies just one provenance-related data element as a core category comprising a core record for an object: Current Location—Repository/Geographic Location. This category is intended to identify only the current or last known owner, a limitation that may well reflect practical experience in art museums in particular: namely, that it is not unusual for museums to know imperfectly the full story of an object's past ownerships and possessions; therefore, recording anything beyond current or last known owner may be highly recommended, but is optional.

The CIDOC CRM identifies two specific classes (or, loosely, elements) that are primed for data reflecting museum understandings of ownership and possession. The classes Acquisition and Transfer of Custody can be used to tease apart the state of having legal and valid right, title, and interest in an object (Acquisition) from that of having transitional custody (Transfer of Custody); both states, as noted earlier, are important for provenance research, documentation, and sharing.

Spectrum identifies units of information (or, loosely, elements) for recording an "owner's personal experience" with an object (such as personal meanings or relevancies) and an "owner's personal response" to an object (such as personal feelings about the object), in addition to identifying expected elements related to ownership history such as the Ownership Exchange Method (gift, purchase), Owner (City Art Museum), and Ownership Dates (1951–2007).

In terms of cataloging practices, several resources—including CDWA, the AAM Guide to Provenance Research,^[16] and Cataloging Cultural Objects (CCO) (http://cco.vrafoundation.org/index.php/toolkit/cco_pdf_version/)—suggest basic principles and expectations for recording and communicating information about provenance: for example, be clear, specific, accurate, attempt to fully account for the history of ownership (to the extent possible), and cite information sources. Getting to the point where it is possible to record and communicate as complete and accurate provenance as possible can take time, diligence, and care. Museum professionals work—over periods of time and through changes in staffing—to reduce incompleteness or imperfections in provenance information to the extent possible, given that the information known and available to a museum at a particular time may be partial, conflicting, inaccurate, or otherwise not entirely satisfactory.

TIME, DILIGENCE, AND CARE

A museum's ability to secure provenance information will depend partly on the priority and standard for documentation and dissemination followed by each previous owner

or possessor, and/or by those with professional or academic interests in objects, such as independent researchers. Each known collecting entity or interested party may have idiosyncratic motivations and practices for documenting and sharing knowledge about previous and current ownerships, possessions, and locations. Museums, for instance, may be motivated to share information in furtherance of public trust, public service, and building historical records for objects. (As noted, museums may have idiosyncratic practices and motivations for sharing provenance, and therefore may have a hand in perpetuating uncertainties.) Other owners may not feel bound or influenced by the same levels of accountability related to collecting activities and documentation expected of and by museums today.

Ascertaining provenance may be a simple exercise if the custodial path is well documented, trusted, and unbroken; as when a living artist sells one of her drawings directly to the first and remaining collector, and sufficient details about the transfer are known. As time passes, and objects change hands and information is exchanged (or not), ascertaining provenance can become complicated. Credible information may be readily available for some periods of ownership (e.g., ample knowledge of the immediate past owner), but the museum professional researching provenance may be challenged by a complete lack of information for other periods of ownership for the same object, and/or by the provision of partial, innocently inaccurate, or possibly manufactured information about still other periods, depending perhaps on the motivations of previous owners to share or withhold information. Museum professionals may need to identify and deal with any red herrings (no matter the source), such as fabricated provenances intended to mislead, or the perpetuation of informed best guesses about certain periods of ownership, or any innocently inaccurate bits of information that have cascaded through oral or written histories of ownership.

Finding Favored Sources

Ascertaining provenance requires familiarity with objects, collections, collectors, and documentation at all levels allowing the researcher to detect what information may be missing in sources and to parse good information from bad. Each successive owner must determine the levels of credibility, completeness, and accuracy of provenance information provided by sources, including information sought or inherited from previous owners. Sought sources for provenance will provide as specific, accurate, and complete information as is known or shareable by the source's author at a given time. A favored source will provide a cluster of credible information describing where, when, and from whom the object originated, and the circumstances surrounding any subsequent changes in ownership and possession.

Some of what is assumed or known about ownership comes from evidence left by previous owners or possessors. Art collectors, for example, use various methods to mark and communicate their ownership of works of art. Collectors might apply unique stamps, inscriptions, inventory or property numbers, or labels directly onto objects in their collections, or might signal ownership by lending objects (along with the owners' names) to exhibitions or by supporting references to objects in publications (e.g., exhibition catalogs and catalogues raisonné).

Some advise museums to get signed statements from sellers regarding provenance (when provenance is known),^[5,17] an action that, if taken, serves museum goals for object documentation and furthering public trust (by helping to show good-faith purchases). Others caution that concerns for liability (as well as damaged reputations) may limit the extent to which sophisticated sellers (such as dealers and auction houses) will commit to statements about provenance, since what is known or understood at a given time about provenance may subsequently be proved inaccurate, if more pertinent information surfaces. Darraby notes, "Those who create a document entitling it 'provenance,' at least within the context of a mercantile transaction, do so at their own peril" (p. 86).^[18]

Museum professionals researching provenance may encounter familiar research challenges related to information availability and accessibility; challenges such as chasing down and getting access to known materials distributed geographically, linguistically, and disciplinarily or discovering along the way that some materials have been lost or destroyed (as may be the case with records of dealers long gone out of business). Custodians of potentially useful materials may do nothing to document and publicize the existence of the materials in order to restrict access, or custodians may simply be unaware of the materials' potential value to anyone else. Not every object carries inscriptions or labels (trusted or not), has been studied, exhibited, or referenced in published or unpublished materials.

When researching provenance for proposed or acquired objects, for instance, museum professionals consult internal records (such as bills of sale, loan receipts, import and export documents, deeds of gift, and curatorial defenses) and may consult external records (personal and corporate papers, inventory lists, photographs, excavation field notes, and oral histories of previous collectors), as well as an array of generally available published materials, such as monographs, catalogues raisonné, journal and newspaper articles, catalogs and announcements related to exhibitions and auctions. The provenances for objects held in other collections sharing some ownership or possession-related context with an object under review by a museum might provide comparable information or clues about provenance, as when, for instance, some stretch of the custodial paths for a group of pendants, earrings, and lockets once held centrally in a private collection, and

now dispersed among several collections, can be traced (backward and forward) through ancestors or descendants of the private collector.

Recent attention on the history and practices around twentieth- and twenty-first-century acquisition of antiquities, archeological objects, and ethnographic materials, and investigations into the custodial paths of objects possibly looted during the Nazi era, has in part fueled interest in maintaining centralized databases or other resources for information about sought objects and sought information, at least through specialized bibliographies, finding aids, and collection catalogs. See, for example, the subscription-based Art Loss Register for stolen objects (<http://www.artloss.com/>), the Object Registry (<https://aamd.org/object-registry>) where museums describe antiquities acquired with incomplete ownership histories, and two examples of freely available databases related to Nazi era looting: the Nazi-era Provenance Internet Portal (<http://www.nepip.org/>) and the earlier referenced database related to museums in the U.K. reporting gaps in provenances (<http://www.collectionstrust.org.uk/collections-link/cultural-property-advice/spoliation>). The AAM Guide to Provenance Research is an example of an existing print publication providing museum professionals with recommendations as well as extensive, annotated lists of resources for investigating changes in ownership or possessions specifically occurring during the Nazi era.

Centralized access to information, if described consistently and made freely available, might provide anyone with an interest in objects—including museum professionals, previous owners, descendants, researchers, lawyers, law enforcement agents—with starting points for investigation; starting points because sources may be in different states of completion and usefulness, with some offering extensive item-level access to needed documents, and others providing limited descriptions, leaving the option of travel to an archive, library, museum, or private collection for direct access to materials, unless restricted or restrictive.

TEMPERED SHARING

Even when information about ownership or possession is readily available, however, that information might be limited to only the most recent transactions or movements, depending on the venue for dissemination. Museum exhibitions and publications commonly identify the current owner of an object through credit lines accompanying object descriptions. A credit line for a drawing by an American artist might read, for instance, Collection Jane and John Doe. Credit lines for museum-owned objects are used, at the very least, to identify the current and immediate prior owner of an object and the means of transfer: for example, Collection City Art Museum, Gift of Jane and

John Doe. This does not tell the full story of an object's custodial path.

Museums, private collectors, dealers, auction houses, and independent researchers may create or perpetuate uncertainties about provenance by highlighting or, alternately, downplaying or suppressing some periods of ownership or possession over others. In the first of two extreme examples, a current owner may greatly value, and therefore want to emphasize, a perceived possession-related connection with a high-profile previous owner, perhaps because the position or reputation of that previous owner is intriguing (e.g., it may be fascinating and beneficial to know and promote the fact that an early-seventeenth-century painting once given to King Charles I of England is now in the collection of an American museum). By contrast, some owners or possessors may be less inclined to share details about previous owners or possessors who have earned notoriety through association with questionable modes of transfer (e.g., the Nazi art dealer Karl Haberstock).^[16] Questionable possessions are equally important to document and share, as knowing each period of ownership or possession may contribute to collective awareness about an object, its custodial path, and caretakers.

Decisions to withhold some provenance information in some venues (e.g., exhibition wall labels or online collection catalogs) may be influenced by motivations to protect commercial interests (if in the business of trading objects) or commitments to respecting requests for confidentiality. Museums and auction houses, for example, are unlikely to freely disclose names of donors or consignors when anonymity is desired, and when no one has yet requested that information. Redacting known provenance information in some cases may be a response to past and continuing assumptions about what people want to know about objects; where it has been assumed that people are very interested in the "back story" for an object: for example, learning about the artist/maker or originating culture, the object itself, and the cultural, historical, archeological, religious, or spiritual significance of the object. Knowing about past owners and possessors may contribute to understanding these significances (and *Spectrum* includes elements for recording an "owner's personal experience" with an object and an "owner's personal response" to an object); however, many museums, previous owners, and other interested parties have demonstrated (and many still demonstrate) a lesser preoccupation with sharing known information about every past and intermediate owner and possessor of an object, at least in public venues like collection, exhibition, or auction catalogs.^[14,15] A sinister assumption is that museums and other owners have in the past not asked about ownership, and not shared what they know, in order to skirt confronting dubious histories of ownership or possession.

One compounding effect of tempered sharing of known provenance—let alone not disclosing known gaps in provenance—is inheritance of light and possibly vague

documentation by subsequent owners and other interested parties and diminished abilities to fully know the story of an object's provenance; a state of awareness that may remain status quo for a long time or may change when information must be revealed, perhaps to comply with information disclosure requirements. More likely, as museums and other interested parties commit resources to researching provenance over time, partial or uncertain information provided by sources or inherited from previous owners might be fleshed out or corrected. Activities surrounding inventorying collections, making new acquisitions, exhibitions, publications, and conserving objects can present museums with ready opportunities and reasons to dig further into what is known about past ownerships and possessions, and to then share that information.

CONCLUSION

Recent calls for museums to share information about provenance more robustly have given profile to ascertaining as complete and accurate provenance as possible, even over time, as part of the diligence and care exercised when acquiring and managing objects. In a good scenario, a complete and accurate picture of the custodial path for an object will have credible, sourced information describing who has held the object in the past, when, where, and under what circumstances. Provenance information alone may not reveal the underlying motivations of an owner to give or accept, to sell, buy or to decline any proposed object. However, knowledge of provenance may improve (or help prove) understandings of rights, titles, and interests in objects from private property to national patrimony; understandings that serve museum goals for object documentation, education, and furthering public trust.

Further still, knowing the full story of an object's history of ownership and possession may contribute to understanding the relative meanings and significances of that object to individuals, nations, groups, and locations, and the object's function within any intended and subsequent contexts. The latter in particular jibes with the assumed interests of museum audiences to know the "back story" for an object, a natural complement to what is happening in museum research, documentation, and dissemination. The message sent in recent years to museums by supporters and observers is for museums to share more of what they know or believe about objects and contexts (including provenance), more widely and more quickly.

Provenance of Rare Books

Marcia Reed

Getty Research Institute, Los Angeles, CA, U.S.A.

Abstract

Just as people have lives, so do books. Like identical twins who end their lives looking quite different, even the seemingly indistinguishable copies of twentieth-century trade books accumulate their own histories and physical characteristics over time from readers' habits and storage conditions. With regard to rare volumes, research on provenance seeks to describe not only books' origins but also their subsequent bibliojourneys as they are read, borrowed, sold, collected, and held by institutions. Unlike studies concerned with the subject matter or content of rare books, provenance investigates the specific histories of individual copies, either by themselves or in the context of larger collections.

A rare book's provenance is the history of its ownership, often elaborating its associations with libraries, private owners, or collections. A significant aspect of book collecting and the history of the printed record of cultural heritage, provenance concerns not only the initial origins of a book but also the ongoing connections to collectors and collections. Research and documentation of provenance deal with two categories of evidence that reveal the histories of individual books. Internal evidence, including marks, inscriptions, bookplates, and bindings, focuses on the physical components of volumes. External evidence, such as catalogs issued by publishers and booksellers and those compiled by libraries, dealers, and auction houses, documents the places and conditions of manufacture, subsequent sales, owners, and collections that held the volumes. Provenance research concerns primarily the authenticity and integrity of rare books; however, in recent decades its data can also be used to develop and write innovative histories of books' circulation, collecting, uses, and reading.

DEFINITION

In the English language, "provenance" refers to the origins of an object, particularly a work of art or an antique. The English and French words are spelled the same and have similar meanings. Both words derive from the Latin verb "provenire," to come forth. However, the root word reverses the direction of contemporary provenance studies that return or seek to go back as far as possible to the object's origins in order to discover proof or, in the best cases, documentation of past owners and locations from the time of an object's conception or production. In French, provenance has been used in commercial and legal contexts, as well as by art connoisseurs, bibliophiles, and book collectors, in the sense discussed in this entry. Provenience is a related term, often used in the same sense of provenance. Archaeologists use it to refer to the precise location or to find the spot of an excavated object.

A rare book's provenance is the history of its ownership, often elaborating its associations with libraries, private owners, or collections. As a significant aspect of book collecting and the history of the printed record of cultural heritage, provenance concerns not only the initial origins of a book but also the ongoing connections to collectors and collections. In the past, research on provenance was seen as an arcane area of interest limited to people who recorded and studied the history of books and collecting.

Those who researched and kept track of provenance were principally librarians and bookdealers, as well as collectors. Like aristocratic family backgrounds and high society connections, distinguished provenances pointing back to a famous collection or library have long been prized by collectors. This aspect of provenance is engagingly described in Frederick Adams' [1969] lecture with occasionally amusing vignettes of collectors among his tales from the world of books. As Adams points out, such "good" provenance affirms the present owners' and collectors' own taste and erudition. Booksellers recorded noteworthy provenances in their catalogs to enhance the interest or value of significant books and to encourage sales. Moving beyond marketing and commercial interests, today, the history of particular copies of books is central to research that seeks to reconstruct a collector's interests, scholarship, and collecting strategies. Provenance can help to define the importance of certain titles or the relationship among books and to create the social histories of reading and collecting.

In its broad contemporary sense, provenance concerns the original owners and all subsequent persons and institutions that acquired books by purchase, gift, inheritance, or legacy up to the present. Borrowed books were occasionally never returned to their owners and libraries. More dramatically, rare volumes were transported from collections in less savory or deliberately illegal ways including

episodes of outright theft. Among other cultural artifacts, books were often taken as spoils; they have been looted during wars and civil unrest up to the present day. Extraordinary dispersals of books and destructions of entire libraries took place during the Reformation with the closure of monastic libraries, as well as during the French Revolution and World War II. Hence, much provenance information has been lost. Amid the disasters of wars, due to the prevalence of plunder and resulting devastation, it has always been the case that cultural conflicts and depredations wreak havoc with the clear views researchers seek to construct of books' and libraries' history.

Early Printed Books

From the invention of Western printing in the mid-fifteenth century to the present, books were printed in various editions or issues, sometimes on different papers. They were often sold in parts or fascicles, held in paper covers or boards. Books' owners frequently had volumes bound according to their own tastes; they and others wrote personal inscriptions denoting ownership (called an *ex libris*) on the inside front cover or on the first pages. Collectors pasted in their specially printed bookplates. Readers and scholars annotated the texts. Wealthy bibliophiles shelved their books in elegantly designed and decorated private libraries, binding the books in specially designed leather covers embellished with coats of arms and other collection-specific ornamentation. Other readers and librarians in religious or educational organizations housed books in less impressive ways. Books from these libraries and institutional collections also frequently bear ownership inscriptions, and they have characteristic (though more modest) bindings and shelf marks on the bindings or edges of pages. Some owners were less careful with their books, using them for professional purposes and/or scholarship. They may have kept books in places where dust, mold, and vermin had their own deleterious effects on the unstable and perishable materials from which books were made. However, such details of condition can sometimes be helpful in identifying books' past history.

As described in the section "Internal Evidence: Physical and Material Qualities," both the materials and physical condition of books can provide primary evidence about past history. Unfortunately for the present interest in provenance, it was not always deemed important for collectors and libraries to preserve the physical integrity of books. As Roger Stoddard writes in the preface to his 1984 catalog *Marks in Books*, up to modern times, binders reassembled books in the course of binding or refurbishing covers. Only rarely did they make a special effort to preserve historical evidence, especially when dealing with books in poor condition. Covers and endpapers were considered to be of little value and they were discarded, taking with them any past library indications and shelf marks,

ownership inscriptions, booksellers' notes and collations, and other annotations. According to Stoddard, "Typically, the only evidence of provenance is on covers and endpapers, so the whole history of the copy may be sacrificed," if indeed books have been restored or rebound.

Modern Editions

Provenance concerns not only early books but also twentieth-century trade books. Although they were published in editions of hundreds or sometimes thousands, these volumes sometimes contain original graphics and specially designed jackets or covers. Their present condition and the marks of provenance that they bear associate them with libraries and collectors in different locales. Signed copies of literary works, variants of book jackets, inserted pages or photos, special bindings, library stamps, collectors' signatures, and booksellers' notations all assist in establishing the history of ownership and location of specific copies. Recently, there is particular interest among collectors in books linked to authors and artists who were associated with twentieth-century avant-garde groups and circles. In turn, the libraries of well-known authors and historical figures can be tracked by their characteristic marks as well as by external documents such as library lists and sale catalogs.

THE STUDY OF PROVENANCE

Provenance research and documentation deal with two kinds of evidence that reveal the histories of individual books. Internal evidence concerns the physical components of volumes. External evidence documents the places and conditions of manufacture, subsequent sales, owners, and collections where the volumes were held.

Internal Evidence: Physical and Material Qualities

Specifics on places of production and means of manufacture provide essential clues that establish the authenticity of books and initiate the chain of provenance history and ownership. Early printed books have associations not only with printers but also with artists, illuminators, patrons, and other participants who played a role in accomplishing the finished volume. When books were offered for sale, printers' and booksellers' lists, in manuscript or printed versions, can provide information about where the books were marketed and where potential buyers lived and worked.

Types of paper and printing ink, page formats, and seemingly pedestrian elements such as folds and sewing styles can all reveal historical information about the place of production. Physical features and formats can indicate whether a book was initially valued highly, collected, and thus bound in an elaborate binding or rather printed for

purposes of public information and record keeping, using less expensive materials and smaller formats. Other books, perhaps those used for educational purposes, were never bound but read and reread as indicated by tattered or heavily annotated copies. In rare but fortunate instances, heavily marked up and seemingly unattractive copies can be traced to historical figures or perhaps editors, sometimes indicating that the copy in hand was a proof copy and a witness of the publication process. Richard Rouse's detailed article on copy-specific features provides examples of marks, marginalia, and other kinds of evidence that he discovered in early books. These held clues that pointed back to early owners, libraries, and related works, which were either bound together as collected works or separated in the process of binding or by greedy dealers who made several books (and sales) from an early collected volume. Similarly, the very rare surviving copies of artists' model books depicting schematic figures and multipurpose decorations and ornaments for use by artists are frequently found with missing pages, cutouts, or pricks that indicate how artists made copies of the designs. In addition, such model books often have spots of paints or inkblots. These could seem to mar the beauty of the original book, yet collectors prize such marks as verifications of books' use by early artists.

All and any indications of ownership are central elements of provenance information that tell about the history of circulation and collection of books. Conveniently for the study of provenance, past owners frequently wrote their names in books, and they made reading notes and personal annotations as well. Collectors and libraries pasted a bookplate inside the front covers to identify their holdings. For locational purposes in their libraries, they affixed a spine label or wrote a shelf mark outside of the volume. These brief alphanumeric notations are found on books' spines or on the page edges if books are shelved on their sides.

Inscriptions: The most obvious evidence of ownership, highly useful to contemporary collectors, are inscriptions. These handwritten notations with full names or initials of owners, dedicatory or presentation phrases, or another mark (occasionally a cipher) most frequently appear on the book's initial pages, particularly the title page. In the simplest form, the owner writes her or his name, occasionally supplying the date when the book was acquired and its price. Several centuries later, such paleographic details can be difficult to read, and considerable research or expertise is needed to decipher them. In early printed books, owners' names were frequently written in their Latin form, with degrees, affiliations with educational institutions, and dedications to others in cases when the books were gifts. Some inscriptions, ciphers, and monograms combine initial letters in decorative calligraphic presentations. In addition, some book collectors inscribed favorite mottos that were related to their family heraldry, or of religious or emblematic significance. Although

inscriptions were frequently effaced as books passed through collections, twentieth-century science (e.g., black light) affords a way to read inscriptions no longer visible to the naked eye.

Bookplates: Owners' names, initials, and mottos may also be found on printed bookplates and labels, again most frequently on the book's initial leaves. The decorative designs of the bookplates comprise heraldic devices, emblemata, images drawn from family history, and, in recent centuries, vignettes that allude to libraries, books, and the practice of reading. Like inscriptions, in many instances, names or initials on bookplates are not immediately comprehensible but must be deciphered with the aid of reference works on bookplates, armorial designs, or initials—of which, fortunately, there are many published compilations. Pasted into the front cover or endpapers, bookplates are usually etched or engraved or printed in relief with woodblocks; occasionally, similar information has been applied with a stamp. Bookplates can be a study in themselves with a substantial literature and specific research strategies that overlap with the historical and art historical areas of genealogy, heraldry, emblems, and ciphers. These highly specialized works on paper (just a few collectors, such as the California bibliophile Estelle Doheny, have had leather bookplates) have been collected as a specific book-related genre for centuries.

Library marks and stamps: Institutional ownership of books was first recorded on the volumes themselves by way of handwritten inscriptions. These often accompanied shelf marks on the outside of each volume (occasionally, shelf marks are seen on the front pages of volumes also). Usually far simpler in their designs than private owners' marks, library marks gave the name of the institution and place. More recent kinds of library marks include embossed names as well as perforations. Although library stamps or deaccession marks of former owners and defunct collections could seem to be irrelevant and were sometimes erased or cut out to eradicate the past historical associations, this practice works against historical research, particularly provenance studies. In fact, marks of past institutional ownership serve to provide highly useful information for tracking provenance.

Heraldry: Marks of heraldry, such as coats of arms, special insignia, and devices associated with court collections and holdings of eminent families, can appear in many places on books but are most frequently found on covers and initial pages. As an important aspect of tracking collectibles, this is an essential element for provenance. Heraldry is an arcane field requiring special expertise because of the necessity for recognizing and deciphering the symbols used in the marks and understanding the protocols for their application.

Bindings: In addition to marks found on pages, book covers are bearers of considerable provenance-related evidence. Paper covers may carry the same types of inscriptions and stamps as the inner pages. Early books with

leather bindings that had notable owners frequently have armorial ornaments or superlibros (ownership stamps on bindings), emblems, or initials applied with binding tools. Embellished by gold tooling with the words “IO. GROLIERII ET AMICORUM” (meaning that a volume belonged to Jean Grolier and his friends), the bindings on sixteenth-century French humanist’s books are among the best known examples of collectors’ bindings. On a grander scale, royal libraries such as those of the French court had characteristic styles of leather bindings marked with identifiable decorations that connected volumes with rulers and family members.

Conservation science: Recent advances in conservation techniques and material sciences not only serve to preserve books but also assist in the analysis of books’ origins. In addition to aiding the identification of printers and publishers when these do not appear on the book itself, specifics on paper stock used for the text block, endpapers, and covers help to locate probable sites or regions of book production and binding. Analysis of paper and coloring also provides solid evidence that the copies of rare books are not recently constituted or newly colored. Further analysis of paper, pastes, bindings, and examination of past treatments assists in ascertaining the integrity of copies, insuring that no pages are inserts or facsimiles. The latter are made easily by means of digital photography and photocopy technology using blank sheets of old paper. Dealers, scholars, and collectors almost always desire complete copies of rare books with all pages intact. However, when books are fabricated from various incomplete volumes, considerations of provenance and bibliography are confounded. Indeed, these “restorations” obliterate books’ history, since they are essentially new assemblages crafted from the spare parts of old or incomplete books.

External Evidence: Inventories and Library Catalogs, Auction Sales Catalogs, and Dealers’ Catalogs

Manuscript inventories and printed lists can document conditions of manufacture, subsequent sales, owners, and collections holding rare books. Valuable accessory information concerning the persons who played roles in making the books (such as papermakers, typefounders and page designers, printers, publishers, and binders) are additional clues that provide historical verification relating to books’ identification and biblio-history. Subscription lists enumerating future owners were printed for prospectuses and later insertions into the completed publications. In addition to collectors, businesses such as dealers and auction houses were central to books’ circulation and, ultimately, to their survival. However, other institutions and social organizations, such as monasteries and missionary societies, were also crucial to the collection and transmission of books. As described in the following text, owners, dealers, and libraries all generate various kinds of lists and

catalogs that provide specific information about individual copies of rare books, serving the study of provenance.
